If it is possible to arrange that one month of the six is spent in the children's department, especially when it has beds for infants, the student will be taught to consider the child in the antepartum department, the labor ward, the maternal cot, the babies' ward and, finally, the children's ward—a continuous picture of this ever changing subject. He will realize that an obstetrician's duty is not merely to produce a living child but that both mother and child must be left at the end of the puerperium in a perfectly healthy condition—the one to take her place in life unhampered by physical disability, the other to grow into a healthy citizen.

BEDSIDE LIBRARY FOR MEDICAL STUDENTS

From "Aequanimitas and Other Addresses," by William Osler.

A liberal education may be had at a very slight cost of time and money. Well filled though the day be with appointed tasks, to make the best possible use of your one or of your ten talents, rest not satisfied with this professional training, but try to get the education, if not of a scholar, at least of a gentleman. Before going to sleep read for half an hour, and in the morning have a book open on your dressing table. You will be surprised to find how much can be accomplished in the course of a year. I have put down a list of ten books which you may make close friends. There are

many others; studied carefully in your student days these will help in the inner education of which I speak:

- I. Old and New Testament.
- II. Shakespeare.
- III. Montaigne.
- IV. Plutarch's Lives.
- V. Marcus Aurelius.
- VI. Epictetus.
- VII. Religio Medici.
- VIII. Don Quixote.
- IX. Emerson.
- X. Oliver Wendell Holmes—Breakfast-Table Series.

TESTS FOR SYPHILIS AMONG COLLEGE STUDENTS

A study prepared by the U. S. Public Health Service, based on blood tests of 78,388 undergraduate students in 515 American colleges, indicates that two out of every thousand students examined are infected with syphilis. This rate is practically the same as that of non-college people of the same age. For the general population of the country, the rate of infection in the age group 15-19 years, based on estimates of the U. S. Public Health Service in November, is about 1.8 per thousand. The apparently higher college rate results from including an unknown number of students in higher age groups up to 24 years in the present survey. Other results of the survey indicated about 15 per cent less syphilis among college women than among men, a difference which it is said parallels the nation-wide prevalence rates by sexes. There was also found a slightly lower rate among college women than among women of the same age group in the population at large. However, little difference was shown between one region in the United States and another for either sex, or between the rates for schools with large as compared to small student bodies. Of the 515 institutions participating in the survey, 219 have facilities for testing the blood of students. Since blood testing in colleges when given are usually made on freshman students, the great majority of those tested were in the age group of 15-19. Two thirds of the college authorities approached in this survey believe that some method of testing the students for syphilis is desirable. A fair proportion of them, however, are still of the opinion that syphilis is bounded by class or racial lines and hence think that blood testing is unnecessary in colleges.

The Strenuous Life.—I wish to preach, not the doctrine of ignoble ease, but the doctrine of the strenuous life, the life of toil and effort, of labor and strife; to preach that highest form of success which comes, not to the man who desires more peace, but to the man who does not shrink at danger, from hardships or from bitter toil, and who out of these wins the splendid ultimate triumph.—*Theodore Roosevelt.*

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Scholarship—Young Applicants Preferred

The award of the Lewis Cass Ledyard Jr. Fellowship is expected to be made by April 1. Applications should be addressed to the Committee of the Lewis Cass Ledyard Jr. Fellowship, The Society of the New York Hospital, 535 East Sixty-Eighth Street, New York City. Preference will be given to young graduates in medicine who have demonstrated fitness to carry on original research. The income, amounting to about \$4,000 a year, will be awarded to investigators in the fields of medicine and surgery or some closely related field. About \$1,000 of this amount will be applied for supplies or expenses of the research and \$3,000 as the stipend. The research work is to be carried on at the New York Hospital and Cornell University Medical College.

Meetings in the Homes of Faculty Members

The Scientific Forum, which is another activity of the Student Activity Plan at Tufts College Medical School, Boston, which meets in the homes of various physicians on the faculty, met January 28 at the home of Dr. Siegfried Thannhauser. Papers were presented by Mr. Thomas F. Broderick Jr., '41, on the use of the x-rays in acute abdominal conditions, and by Miss Marguerite L. McKay, '41, on sterility in the female. The society met at the home of Dr. Louis E. Phaneuf, February 11, when Mr. Peter S. Zarecki Jr., '41, read a paper on anemias of pregnancy, and Mr. John J. Talinski, '41, on displacements of the pelvic organs following childbirth. Later in February the forum met at the home of Dr. Benjamin Sachs, when two papers on ophthalmology were presented by Mr. Edward Joseph Howley, '41, and Mr. Paul J. Coughlin, '41.

Harvard Expands Work in Legal Medicine

The dean of Harvard University Medical School, Boston, Dr. C. Sidney Burwell, announced, January 26, in his annual report that Harvard University Medical School has undertaken expansion of its work in legal medicine and will train a small number of men who desire to specialize in that field. The Harvard Law School is cooperating in the expansion, the two schools offering a course for undergraduate medical students, giving a survey of the field of legal medicine and the essentials of medical jurisprudence. New laboratories are being set up for this department in that portion of Harvard Medical School in which there is already located the George Burgess Magrath Memorial Library of Legal Medicine. Dr. Alan R. Moritz, who spent the last two years abroad studying the organization and practice of legal medicine in European countries, will be in charge of the department. He is the first to hold the professorship of legal medicine established at Harvard in 1936 in honor of the late Dr. George Burgess Magrath, pioneer in this field. Dr. Moritz was formerly chief pathologist at the University Hospitals, Cleveland, and associate professor at Western Reserve University. This department will also provide an interesting example of cooperation among the three medical schools in Boston, as the lectures will be attended also by third year men from Tufts Medical School, and next year it is expected that medical students from Boston University will also participate.

Loan Fund for Students at Colorado

Dr. Frank W. Kenney, Denver, has presented to the University of Colorado \$3,000 in the form of 4½ per cent bonds of the Pennsylvania Railroad to constitute a loan fund, the income of which is to be used to assist worthy students in the medical school. Preference is to be given to eager and ambitious boys in the junior and senior years, although the donor's preference is not to be considered mandatory. Loans are to be at a moderate rate of interest and are not required to be evidenced by a legal obligation payable at a given time. The student will, however, agree to repay the loan as soon as he can. Selection of students who shall receive such loans will be made by a committee of three, which at present comprises Drs. James J. Waring, George B. Packard and Casper F. Hegner, all of Denver. Vacancies in the committee will be filled by the trustees of the Medical Society of the City and County of Denver.

Scholarships Awarded at Columbia

Dean Willard C. Rappleye, of Columbia University School of Medicine, New York, announced October 19 the award of scholarships for the present academic year to the following students, among others. The winners received their premedical training in various colleges and universities in many different states and Puerto Rico. William J. Welch, of Yale, won a grant of \$900, and Alando J. Ballantyne, University of Arizona, \$600. Among those awarded resident scholarships of \$500 each were: Carroll L. Conley, Johns Hopkins; Fred M. Davenport, Columbia; John J. Hutchinson, University of Illinois; Wilson W. Schier, Lawrence College; Freeman Irby Stephens, Columbia; Abraham Geffen, Emory; Virginia M. Goddard, Tufts; George L. Hawkins Jr., University of Missouri; Milton B. Smith, University of California; Howard A. Blazar, Brown; Stanley W. Burwell, Columbia; Thomas P. Hennelly, Holy Cross; Bayles R. Kennedy, University of California; Eugene C. McCann, Tufts; William G. Schoch, University of Arizona; Roland G. Tremblay, University of New Hampshire, and Orrin J. Van Dyk, Harvard.

Among those awarded scholarships of \$500 each were: William T. Adams, Utah State; Archibald G. Fletcher Jr., Princeton; Fay P. Greene, Southwestern; Louis Nash, University of Nevada; William E. Owen, Cornell College, Mount Vernon, Iowa; David T. Dresdale, Brown; Irvin H. Trinchler, New York University; Aldred Dusehatko, Columbia College; John Milne, Dartmouth; Theodore Gold, Columbia College; John Dean, Yale; Edward H. Townsend Jr., Harvard; Alden K. Boyd, Cornell; Gustav Bansmer, Columbia College.

Stuart W. Cosgriff, Holy Cross; Paul A. Kirschner, New York University; Charles G. Zubrod, Holy Cross, were awarded scholarships of \$400 each, and Kenneth B. Wright, Columbia College, and John J. Ryan, New York University, scholarships of \$350 each.

Christmas Party at Louisiana

The first Christmas party in the history of the School of Medicine of Louisiana State University, New Orleans, was held December 22 when faculty members, secretaries, technicians, and others on the staff, met in the library which was decorated for the occasion. Dr. Charles Midlo, master of ceremonies, made "a highly amusing opening talk." A sextet including

among others Drs. W. K. Hall, bass, and Edgar Hull, tenor, sang; candy and punch were served and there were gifts for each one present. At the conclusion of the party, Dr. B. I. Burns, dean of the school, made a speech and announced that the Christmas holidays for all the staff members would extend from Friday evening until Wednesday morning after Christmas.

The Ephraim McDowell Memorial Home

The Kentucky State Medical Association dedicated in Danville in May the home of Ephraim McDowell, in which house he performed the first ovariectomy in 1809 (Student Ephraim McDowell, *THE JOURNAL*, Dec. 24, 1938, p. 2441). Dr. Charles A. Vance, Lexington, chairman of the council of the Kentucky State Medical Association, presided at the dedication, and Dr. Irvin Abell, Louisville, past president of the American Medical Association, gave the principal address. The home was accepted for the state by Governor A. B. Chandler. Dr. Edward P. Heller, Kansas City, Mo., represented the Missouri State Medical Association at the dedication. Dr. Edward V. M. Mastin, St. Louis, the great-great-grandson of Ephraim McDowell, who represented the Southern Surgical Association, and Dr. James D. Hancock, Louisville, acting president of the Kentucky State Medical Association, were among the speakers. Dr. Louis Frank, Louisville, past president of the Kentucky State Medical Association, presented to the home the Arch Barkley Memorial Gifts. The home and its treasures, including among other things the surgical instruments used by McDowell, then passed into the keeping of the Department of Parks of Kentucky. Here is not only the room in which McDowell operated on Mrs. Jane Todd Crawford, but the old well in the garden, the servants' quarters, the kitchen and the now famous door knocker which was used by patients in all walks of life, including James K. Polk, who later was President of the United States.

Annual Meeting of Association of Students

Including delegates, visitors and observers, about 300 persons attended the fourth annual meeting of the Association of Medical Students in Detroit, December 27-29. The delegates represented some twenty American medical schools. The present paid up membership of the Association of Medical Students is said to be about 2,400. At this meeting, Thomas L. Perry Jr., Harvard Medical School, '40, was elected president. The vice presidents elected were Leopold M. Trifari, Tufts College Medical School, '42; Edmund M. Braun, New York University College of Medicine, '41; Jane B. Oldden, Woman's Medical College of Pennsylvania, '41; Joseph H. Haffenshiel Jr., Johns Hopkins University School of Medicine, '41; John H. Cordes Jr., Emory University School of Medicine, '41; Paul H. Gray, Rush Medical College, '41; Thaddeus J. Bugelski, University of Buffalo School of Medicine, '41; Henry A. Caraco, Washington University School of Medicine, '41; William M. Christophersen, University of Louisville School of Medicine, '42, and Charles Roberts, of the Royal College of Edinburgh. Clifford A. Sager, New York University College of Medicine, '41, was elected chairman of the editorial board of the *Journal of the Association of Medical Students*, and Herbert F. Waldhorn, New York University College of Medicine, '42, editorial director.

Among the resolutions adopted was the following concerning student aid:

WHEREAS, The high cost of a medical education makes it difficult for many students to equip themselves completely, this council for many students to equip themselves completely, this council reaffirms its stand on supporting local efforts "in the establishment of scholarships, student loan funds, and other methods of meeting the problem of the tremendous cost of medical education."

A spontaneous movement arose among the medical students at this meeting suggesting the possible fusion of the Interne Council of America with the Association of Medical Students, but final official action was not taken at this meeting.

At this meeting, the American Youth Congress extended to the Association of Medical Students an invitation to become a cooperating organization. After a spirited discussion a decision was reached to have local chapters of the association cooperate with the American Youth Congress in their locality and also to have the lay education committee of the Association of Medical Students continue its cooperation with the American Youth Congress without having the Association of Medical Students constituted a cooperating organization with the American Youth Congress.

The delegates made a tour through the River Rouge plant of the Ford Motor Company. On the second day a special feature was the presentation of the prize winning clinics conducted under the auspices of Wayne University chapter of the association. One of these was a colored movie of the "Physical Diagnosis and Examination of the Skeletal Musculature," prepared by Fred Margolis, '40, and a group of members of the association from Wayne University, and the other a model surgery clinic presented by Kenneth Campbell, '40, and another group of Wayne students. In addition to these demonstrations there was a program of clinics at the medical school amphitheatres.

Tufts Plans Revision of Premedical Course

Revisions in the premedical studies have been planned jointly by the chemistry and biology departments at Tufts College, Medford, Mass., and are expected to be ready to go into effect next fall, the *New York Times* reports. The chief objective of the curriculum is not only to give future medical students the best possible training for professional study but also to allow them greater latitude as undergraduates for cultural development. One of the most significant changes will be the elimination of the departmental majoring, as such, in chemistry and biology. The new plan will attempt to correlate the undergraduate work in college, wherever possible, with the course of study in the professional or medical school. It has been planned so that all the requirements will be completed in the first three years; the fourth year will be left free for electives, either in additional scientific study or, as the faculty would prefer, in cultural subjects. It is also planned to have premedical students advised by six men, three each from the departments of chemistry and biology, whereas at present these students are advised only by the head of the department.

Fees at Oregon

Fees and deposits paid by students at the University of Oregon Medical School, Portland, according to the catalogue of the school, are as follows:

Regular Fees	
Matriculation fee (not refundable).....	\$ 5.00
Resident tuition and laboratory fee, per term.....	95.00
Nonresident tuition and laboratory fee, per term.....	115.00
Building fee, per term.....	5.00
Deposits	
Deposit to reserve place in entering class.....	\$ 20.00
Breakage deposit—first and second years.....	15.00
Breakage deposit—third and fourth years.....	10.00
Special Fees	
Graduation fee.....	\$ 6.50
Late-registration fee.....	\$1.00 to 5.00
Penalty for late payment of tuition fees (full payment).....	minimum 2.00
Transcript fee.....	1.00

Vote to Drop the M.B. Degree

At a meeting of the entire student body of the school of medicine of Louisiana State University, New Orleans, in the assembly hall of the new Charity Hospital, the dean announced that the executive committee of the school of medicine has approved a proposal to confer the M.B. degree on graduates no longer but to grant the M.D. degree on the satisfactory completion of the fourth year. The Executive Committee felt that the action of the Louisiana State Board of Medical Examiners in requiring a year's rotating internship of all candidates for licensure in Louisiana makes it unnecessary for the school of medicine to require this service before it confers the M.D. degree. According to the *Tiger*, the Executive Committee will recommend to the administration of the university that the change become effective this year.

Equipment Required at Stanford

Medical students at Stanford University School of Medicine, San Francisco, are required to have the following equipment:

SECOND YEAR STUDENTS

Stethoscope (Ford)
Percussion hammer
Hemocytometer
Hemometer
Metal tape measure

THIRD YEAR STUDENTS

Sphygmomanometer (Tyco)
Ophthalmoscope
Otoscope
Head mirror 3½ inch diameter and one-half inch aperture and band
Nasal speculum (Vienna model)
Nasopharyngeal mirror No. 9
Laryngeal mirror No. 4
Ear speculums (Toynbee, nest of three)

Premedical News

Dr. Robert U. Patterson, formerly Surgeon General of the U. S. Army and now dean at the University of Oklahoma Medical School, Oklahoma City, was the principal speaker at a meeting of the Oklahoma Alpha chapter of Alpha Epsilon Delta, an honorary fraternity for premedical students, in Oklahoma City, December 7. His subject was "The Fields of Medicine Open to the Young Doctor"; other speakers at the meeting were Samuel W. Reaves, dean of the School of Arts and Sciences, whose subject was "The Layman's View of Medicine," and J. T. Self, who spoke on "The Status of the Premedic." Seventeen Oklahoma students were initiated into the local chapter on this occasion. On November 7 the Alabama Alpha chapter of this premedical fraternity awarded a silver cup to Harry O'Rear, of Jasper, Ala., for having made the highest average in biology and chemistry during his freshman year.

Scholarships and Prizes at Wayne University

The Alumni Association of Wayne University College of Medicine, Detroit, has subscribed an endowment fund that provides for research grants, student loans and scholarship prizes. Undergraduate scholarships are granted to a number of deserving students on a student loan basis, after investigation by a special scholarship committee in conjunction with the board of trustees of the alumni association. Applications must be from the junior and senior classes. The Alumni Association gives a prize of \$50 to the senior student who has the best scholarship record through the four years. The Alumni Association also offers an annual prize of \$50 for the best scientific work done during the year by a recent graduate.

Dr. Ranson Will Give the Dunham Lectures at Harvard

Harvard University, Cambridge, Mass., announces that a series of Edward K. Dunham lectures will be delivered at the medical school, March 4, 6 and 8, by Dr. Stephen W. Ranson, director of the Neurological Research Institute at Northwestern University Medical School, Chicago. All members of the medical school and other interested professional persons are invited. Dr. Ranson was head of the department of anatomy at Northwestern University Medical School from 1912 to 1924, was head of the department of neuro-anatomy and histology at Washington University Medical School, St. Louis, from 1924 to 1927, and then returned to Northwestern University Medical School. Dr. Ranson is a member of the editorial board of the *Archives of Neurology and Psychiatry*, which is published by the American Medical Association, and is the author of a well known book, "The Anatomy of the Nervous System."

Scholarships and Assistantships at St. Louis University School of Medicine

Students showing special proficiency in the first two years at St. Louis University School of Medicine, St. Louis, are eligible for appointments, as assistants, who take part in teaching and research under the supervision of the departmental director. To be appointed to an undergraduate assistantship, the applicant must agree to accept the appointment for four years and to devote half of his time to assigned duties in a chosen department. The students so appointed rank as junior assistants during the first two years and as assistants during the third and fourth years. The appointee is free from tuition for the four years and receives an annual salary ranging from \$250 to \$350.

The Dr. Samuel T. Lipsitz Scholarship of \$150 a year is awarded to a selected student. The Levi and Peppe Wolfert Scholarship is awarded annually for the purpose of assisting a needy student and also to help in . . . ally gifted one.

Student Aid Fund awards \$50 a year to a student in need of special assistance.

In addition, St. Louis University School of Medicine offers a number of graduate fellowships in the basic sciences and in the clinical sciences. Inquiries concerning these matters should be addressed to the Dean of St. Louis University School of Medicine, St. Louis.

Scholarships at Yale

Certain Yale University funds are available in part for financial aid to students in the school of medicine. Some of the scholarships available are as follows:

The Judson Bardwell Memorial Scholarship.
The Edward Thomas Cathoun Scholarship, for work in pathology.
The Annie G. R. Garland Memorial Scholarships. Awarded to worthy students in the graduate and professional schools of the University who are chosen primarily because of their ability, character and promise of future usefulness and the quality of their work.
The James Raymond Goodrich Memorial Scholarships.
The Joseph Hendley Townsend Scholarship.
The Flora Adler Ullman Memorial Scholarship Fund.
The Rosa Verdi Scholarship.

Lecture to Marquette Students

Dr. Julius Baner, clinical professor of medicine at Louisiana State University School of Medicine, New Orleans, and formerly of Vienna, addressed the students of Marquette University School of Medicine, Milwaukee, January 23, and also gave the Louis M. Warfield Memorial Lecture in Milwaukee, sponsored jointly by the Milwaukee Academy of Medicine, the Milwaukee Internists' Club and the Wisconsin Anti-Tuberculosis Association.

Repercussions of International Events

The regular student body of Harvard Medical School, Boston, shows some repercussions of international events, with a slight drop in numbers registered from Canada and China. In recent years there has been an increase in the number of men from the Latin American countries. The student body of 522 has men from Argentina, Guatemala, Colombia, Canada, South Africa, Siam and Germany; last year there were two men from Finland in the student body, two from France, three from Belgium, four from London and one each from Germany, China, Wales, Hungary and Chile.

Tulane Students Honor Retiring Dean

A meeting of the student body of Tulane University School of Medicine, New Orleans, and the faculty members was held January 27, in the Richardson Memorial building to honor Dr. Charles C. Bass on the eve of his retirement after eighteen years of service as dean of the medical school. On behalf of the students, Edward R. Villemez, president of the student body, presented a portrait of Dr. Bass to the university. Following the student's meeting, the faculty attended a luncheon where Dr. Rudolph Matas, professor emeritus of surgery, presented to Dr. Bass a scroll from the faculty. Dr. Bass is a native of Mississippi and graduated from Tulane University School of Medicine in 1899, joining the staff in 1904. In 1912 he went to Panama on an expedition, under the auspices of the department of tropical medicine, to continue his studies on malaria. He is said to have been the first successfully to cultivate the malaria parasite *in vivo*. He has done research also on hookworm, pellagra, beriberi and typhoid fever and is still active in research work. Dr. Bass has been president of the American Society for Clinical Investigation, the American Society of Tropical Medicine, and the Southern Medical Association. He was awarded the honorary degree of doctor of science by the University of Cincinnati in 1920 and the honorary degree of doctor of laws by Duke University in 1937.

Loan Funds at the University of Tennessee

The University of Tennessee College of Medicine, Memphis, has several loan funds whereby small sums may be lent to worthy students who have demonstrated their scholastic competency. A prize known as the Faculty Gold Medal is awarded each year to the graduate whose general record throughout the twelve quarters' course has been most satisfactory. There is also the Judge H. T. Ellett Scholarship, which is intended to make possible the study of medicine for some worthy Mississippi student who otherwise would not be able to pursue this work. Applications should be made to the office of the dean.

Medical College Restores Original Building

Founders Day at the Medical College of Virginia, Richmond, January 16, was marked by the dedication of the Egyptian Building, the first permanent home of the school, which has been recently restored. The college opened its doors in 1838 in an old remodeled hotel, but in 1845 a new building done in the Egyptian manner was completed and dedicated. After continuous use since its dedication the building had fallen into disrepair. Through the generosity of Mr. Bernard Baruch, New York, the building has been reconstructed. A new auditorium has been named for Mr. Baruch's father, Dr. Simon Baruch, who graduated from the school in 1862. The auditorium and the lobby on the first floor are in Egyptian design. The

upper floors are arranged for the departments of bacteriology and pathology for teaching, diagnosis and research. The program for the dedication included addresses in the morning by Drs. Walter H. Judd, until recently a missionary in China, on "Chinese Medicine" and Wyndham B. Blanton, Richmond, on the history of the Egyptian Building. In the afternoon the Brown Séquard Society presented Dr. George W. Thorn, Baltimore, who spoke on "Studies of the Adrenal Cortex" in the new auditorium. The evening program consisted of an address at the Richmond Academy of Medicine by Elmer V. McCollum, LL.D., Baltimore, on "The Place of Vitamins in the Maintenance of Normal Health."

Average Expenses at University of Chicago

An estimate of the average expenses in attending the medical schools at the University of Chicago for each quarter includes: rent and care of room, \$60; board, \$82, textbooks and supplies, \$25, laundry and cleaning, \$25; registration and health service fees, \$6, and incidentals, \$35, making a total of \$233, exclusive of tuition fees, which are \$150 a quarter.

Temple's Student Body

The current enrolment at Temple University School of Medicine, Philadelphia, totals 446 students from twenty-six states, Puerto Rico and Hawaii and represents 148 colleges. Physicians have enrolled seventy-one of their sons and daughters in the medical school. Of the 446 students, twenty-three are transfers from two year medical schools; thirty of the students are girls.

Dr. Keeton Elected to National Board of Examiners

Dr. Robert W. Keeton, Chicago, professor of medicine, University of Illinois College of Medicine, has been elected a member of the National Board of Medical Examiners to succeed the late Dr. Charles A. Elliott. Dr. Keeton is one of the first diplomates of the board, holding certificate No. 25. He graduated from Northwestern University Medical School in 1916.

Scholarship Fund at University of Georgia

The Charles McDonald Brown Scholarship Fund is available to students at the University of Georgia School of Medicine, Augusta, for the purpose of aiding them in defraying the expenses of their education. The interest on this fund is lent to worthy young men on condition that they obligate themselves to return it with 4 per cent interest.

Wisconsin State Board Questions

The following questions in surgery were given at the examination held in Milwaukee, June 27-30, 1939, by the Wisconsin State Board of Medical Examiners:

1. What facts are necessary to diagnose stone in urinary tract? Give treatment.
2. Why are fractures of pelvis serious? Briefly summarize treatment.
3. Describe in detail your surgical treatment of severance of all tendons on anterior side of wrist.
4. Discuss carbuncle—cite common locations—dangers and surgical treatment.
5. How would you prepare skin for a major abdominal operation? How would you prepare your own hands for the same job?
6. What is gas gangrene? Discuss cause, pathology and treatment.
7. Give the causes, symptoms and treatment of septic peritonitis.
8. In skull fractures, give symptoms, dangers. Discuss briefly your management thereof.
9. Discuss pleurisy with accumulation of pus. Give treatment.

Only eight of the nine questions were to be answered.

PROBLEMS IN THE TREATMENT OF ADVANCED TUBERCULOSIS IN A MUNICIPAL HOSPITAL

BASED ON AN ANALYSIS OF THE COURSE OF
DISEASE AND RESULTS OF PNEUMO-
THORAX TREATMENT

HERMAN EPSTEIN, M.D.

AND

H. W. HETHERINGTON, M.D.

PHILADELPHIA

From the point of view of the public health, isolation and treatment of patients with clinical disease constitute important factors in the control of tuberculosis. Many patients prefer to remain at home under the care of private physicians or clinics, a procedure that may be justified if sputum can be kept negative for tubercle bacilli or if adequate measures are taken for the protection of persons in contact. For the majority of patients, however, institutional care is advised. Most communities provide sanatorium facilities for patients with more favorable prognosis. Infectious patients with advanced disease and less favorable prognosis are usually cared for in special wards of local hospitals, the major objective being the removal of these individuals from contact with the community.

In some municipalities, collapse therapy is employed as a partial solution of the lack of sanatorium facilities. Suitable patients are admitted to an institution until collapse is established. If the sputum is rendered negative or if a satisfactory collapse appears probable, the patient is discharged to a dispensary for the continuation of artificial pneumothorax with rest in bed at home and the supervision of public health nurses to supplement the treatment. Through the use of so-called ambulatory pneumothorax, sanatorium waiting lists are relieved and the number of sputum-positive patients in the community is reduced. Hruba¹ recently reported the extent to which this method of tuberculosis control is employed in Chicago. Although it is not ideal treatment, its value is to some extent proportional to the lack of beds for institutional care.

It is a problem to know to what extent treatment, particularly collapse therapy, should be applied in the hospital to patients admitted primarily for purposes of isolation. To patients with advanced tuberculosis whose prognosis is apparently hopeless there is a tendency to apply artificial pneumothorax because it is felt that the patient will surely die without some form of "active" treatment. Collapse therapy is instituted in

the hope that improvement, however improbable, may be the result. In over zealous efforts to help these patients, more harm than good may be done. In this paper an attempt has been made to determine the indications and limitations of collapse therapy for patients in the tuberculosis wards of a large city hospital.

A series of 504 patients discharged consecutively from one of the services of the Department of Tuberculosis of the Philadelphia General Hospital during the three year period 1935-1937 has been reviewed. Pulmonary tuberculosis was diagnosed in 441, or 87.7 per cent, of cases.

Artificial pneumothorax was attempted in 137 instances, but in seventeen of these no free pleural space was found. The remaining 120 cases in which pneumothorax was established constituted 27 per cent of the cases of pulmonary tuberculosis. Table 1 shows the stage of disease and the results of sputum examinations on admission of the patients to the hospital in the total group and in those in whom pneumothorax was subsequently established. The great majority of patients, 352, or 79.9 per cent, had far advanced lesions.

Tubercle bacilli were found in the sputum of 377, or 85.4 per cent, of the total group and in 106, or 88.3 per cent, of the pneumothorax group. The large number of patients with far advanced, sputum-positive disease stresses the importance of a city hospital in the removal of foci of infection from the community. It likewise follows that pneumothorax is indicated in a relatively small proportion of cases and that the value of this form of therapy is limited.

Unfortunately many patients with sputum-positive tuberculosis fail to remain in the hospital and return to their homes, where they act as foci for the further spread of the disease. Of the 441 tuberculous patients 247, or 56 per cent, remained in the hospital less than ten weeks, 392, or 87 per cent, remained less than seven months and twenty-seven, or only 6 per cent, remained more than one year.

Table 2 shows the reasons for discharge of white and colored patients in both the total and the pneumothorax groups. Death occurred in the hospital in 190, or 43 per cent, of patients. It was the cause of discharge of 33 per cent of white and 52 per cent of colored patients.

Of the white patients 28 per cent and of the colored patients 31 per cent left the hospital against advice. However, these percentages, which are almost equal, require further analysis. After subtracting the discharges due to death there remain 142 white and 109 colored patients who either accepted treatment or left against advice. It now appears that sixty, or 40 per cent, of the 142 white patients and seventy-one, or 65 per cent, of the 109 colored patients left against advice, a fact showing that actually there is a decided differ-

From the Philadelphia General Hospital and the Henry Phipps Institute of the University of Pennsylvania.
1. Hruba, Allan J.: Collapse Therapy of Tuberculosis, *Am. Rev. Tuberc.* 40:255 (Sept.) 1939.

ence between the two groups. It is the large number of patients who leave against advice that limits the value of the hospital in its function of protecting the community.

Artificial pneumothorax was attempted in 137, or 31 per cent, of the 441 tuberculous patients, and some degree of collapse was obtained in 120, or 27 per cent. It has already been intimated that not infrequently this form of treatment was tried because the prognosis with

rest treatment alone was considered to be very poor. In table 3 the degree of selective collapse in the 137 cases in which pneumothorax was attempted is indicated. This was evaluated by x-ray examination at the time of optimal collapse, obtained by pneumothorax alone or with the aid of pneumonolysis. As shown in table 3, there was no significant difference between white and colored patients in the probability of obtaining a good collapse. A satisfactory anatomic collapse of the diseased portion of the lung was shown by x-ray examination in twenty-six, or 19 per cent, of patients; that is, approximately one in five.

RESULTS OF PNEUMOTHORAX TREATMENT

Most authorities are of the opinion that the results of treatment should be evaluated only after a five year period of observation. In the type of hospital patient with which we are dealing it is difficult to fulfil this requirement. Since the majority remained under observation for only a short time, it was decided to separate patients into two groups, depending on the length of hospitalization. Ten weeks was arbitrarily chosen, because if the period was longer the number of patients remaining for whom results could be evaluated would be too small. Although ten weeks is a very short period, it should be pointed out that of the seventy-seven patients for whom the results of pneumothorax treatment have been evaluated, sixty-five, or 84 per cent, were under observation for more than five months and forty-one, or 53 per cent, were under observation from one to five years.

There were eighty-eight patients in whom pneumothorax was attempted who were under observation for more than ten weeks, including eleven in whom no space was obtained and seventy-seven in whom pneumothorax was continued. In evaluating the results of pneumothorax treatment, only these seventy-seven patients are considered. Although this constitutes a very small series in comparison with others that have been reported from institutions for the care of tuberculosis, it is believed that the series here under consideration merits report as an indication of what may be expected in the tuberculosis wards of a large general hospital under the conditions obtaining today.

In table 4 the results of treatment in the seventy-seven cases are considered in relation to the type of pneumothorax space. The results of treatment were determined by x-ray examination and by clinical cri-

teria. In sixty-four instances there were open cavities, of which twenty-two, or 34 per cent, were apparently closed by collapse therapy. Of the sixty-seven patients with positive sputum twenty-one, or 31 per cent, became sputum negative. The sedimentation rate showed improvement in 64 per cent, and there was a gain in weight in 53 per cent of patients.

It has already been shown that approximately one in five of all patients on whom pneumothorax was attempted obtained a satisfactory collapse. It is among the small number of patients who received a good collapse that most satisfactory results followed, improvement occurring in 87 per cent. On the other hand, only 29 per cent of those with a fair space and 23 per cent of those with a poor space were improved. It is interesting to note that of the eleven patients observed more than ten weeks in whom pneumothorax could not be established, three, or 27 per cent, were improved, this percentage being approximately the same as the percentages found for patients with a poor or a fair pneumothorax space. The group in whom pneumothorax was established was made up of thirty-two colored and forty-five white patients. Analysis of the records of the eight colored patients who improved shows that six had a good collapse and two had a fair collapse, while no patient with a poor collapse had this result. On the other hand, of the twenty-eight white patients who improved, thirteen, or 46 per cent, had a good collapse, ten, or 36 per cent, had a fair collapse and five, or 18 per cent, had a poor collapse.

In an attempt to control widespread disease, bilateral pneumothorax was given in sixteen, or 21 per cent, of seventy-seven cases that are being discussed. Eight of these patients were improved, all of them having been under observation for more than two years. In six instances there was a good bilateral collapse and in two instances there was a good collapse on one side and a fair collapse on the opposite side. On the other hand, of the eight patients who were unimproved, only

two had a satisfactory bilateral collapse. One of these was under observation for ten weeks only, while the other, after making an excellent improvement for more than two years, died suddenly of heart failure. Accordingly, it is apparent that every patient who improved had an anatomically satisfactory bilateral collapse, while of those who were unimproved this was true of only two of eight patients.

The results with the seventy-seven patients with artificial pneumothorax, including sixteen whose treatment was bilateral, indicate, therefore, that a pneumothorax with an anatomically satisfactory collapse is an important factor in controlling the disease and that in the

absence of an anatomically satisfactory collapse improvement is not likely to occur. If this fact is borne in mind it will help to determine where useful work ends and useless work begins.

COMPLICATIONS OF PNEUMOTHORAX TREATMENT

In order to determine the advisability of pneumothorax treatment in the type of patient under consideration, it is necessary to discuss the frequency with which

complications are apt to occur. In this series there was one instance of pleural shock. After being apparently dead the patient recovered following artificial respiration and intraeardiac injection of epinephrine hydrochloride. Spontaneous pneumothorax of seven patients as a result of treatment in the hospital occurred. Two patients died of this complication, a third developed empyema and another developed a massive effusion, while the remaining three suffered no serious effects.

The most frequent complication affecting pneumothorax is adhesions between the visceral and parietal pleura. Of the 137 patients in whom pneumothorax was attempted, seventeen had no free pleural space. Of the remaining 120 patients forty-one, or 34 per cent, had adherent pleura, in most instances sufficiently extensive to interfere with satisfactory collapse. There were an patients with adhesions of clinical significance, about one third of whom received pneumonolysis. In other words, a total of seventy-eight, or 65 per cent, of those who received pneumothorax treatment had either adherent pleura or adhesions interfering, to some extent at least, with collapse. Progressive obliterative pleuritis occurred in twelve cases during the period of our observation. Preceding the adhesive pleuritis, a free pleural space had been present in four instances, while eight had been complicated by adhesions or adherent pleura.

During hospital observation fluid in the pleural cavity, sufficient in amount to be of clinical significance, occurred in twenty-two, or 18 per cent, of those receiving pneumothorax, eight of these patients requiring aspiration. In fifteen, or 12.5 per cent, of cases there was a small amount of fluid confined to the costodiaphragmatic sulcus. The total number in which fluid was noted was thirty-seven, or 31 per cent.

Cardiac embarrassment due to pneumothorax treatment not infrequently occurs, as a result either of over-collapse or of cardiac displacement. Overcollapse is more likely to occur in spontaneous pneumothorax, in bilateral collapse or in unilateral collapse in which there is insufficient functioning lung, usually due to extensive disease on the opposite side. There were three deaths due to cardiac failure. These three cases emphasize the importance of bearing in mind constantly that pneumothorax treatment does not affect the lungs alone but the cardiorespiratory mechanism. It is important not to think entirely in terms of anatomic collapse, overlooking the significance of the physiologic changes produced.

Twenty-four of the 120 patients who received pneumothorax treatment died. The causes of death may be divided into two groups: progression of the tuberculous disease, and complications arising as the result of collapse therapy. There were fifty patients whose disease continued to progress during the course of treatment. Of these, seventeen died in the hospital as a result of the progression. Of the seven patients that died of complications, four died of spontaneous pneumothorax; in two instances they had been admitted with this condition following treatment elsewhere. The three remaining deaths were due to heart failure, one following a fourth stage thoracoplasty. In other words, of the seven patients four, or 3.3 per cent of the total, died of complications resulting from pneumothorax treatment given in the hospital.

The information in the preceding paragraphs indicates that complications are relatively common among patients with advanced disease. Since complications may nullify the value of treatment, the frequency with which they occur should be taken into consideration in attempting to decide the advisability of pneumothorax treatment of these patients.

SUMMARY AND COMMENT

The principal function of local hospitals for tuberculosis is to remove from the community patients with far advanced disease, this being part of the general plan of preventing the spread of tuberculosis by isolation of sources of infection. These patients with poor prognosis present a difficult therapeutic problem. It is important to decide the extent to which treatment is advisable in order to determine the point at which useful work ends and useless work begins. Particularly in the application of collapse therapy, much time may be spent by the physician doing discouraging work that not only fails to benefit the patient but may be actually harmful.

A series of 504 patients discharged consecutively from one of the services of the Department of Tuberculosis of the Philadelphia General Hospital has been analyzed. Many of the patients were admitted in a hopeless condition, since this department of the hospital is intended to treat patients considered unsuitable for sanatorium care. Approximately 80 per cent of the tuberculous patients had far advanced disease, and more than 85

TABLE 4.—Results of Treatment Related to the Character of Collapse of the Diseased Portion of the Lung

	Number	Number Improved	Per Cent Improved
.....	26	6	23
.....	25	5	20
.....	23	29	87

per cent had tubercle bacilli in the sputum. The high proportion of sputum-positive patients emphasizes the importance of a city hospital for tuberculosis in protecting the community by removing the patients most likely to spread the disease. Pneumothorax treatment was given to 120, or 27 per cent, of the tuberculous patients. Far advanced disease was present among 84 per cent and positive sputum among 88 per cent of those receiving pneumothorax treatment.

Refusal of patients to remain in the hospital constitutes one of the greatest difficulties both in the treatment of the individual case and in the protection of the community. A majority of patients remained in the hospital less than ten weeks, 87 per cent remained less

than seven months and only 6 per cent remained more than one year. Excluding those who died, 65 per cent of the colored and 40 per cent of the white patients left the hospital against advice. In Philadelphia infectious patients who are a menace to others are not compelled to enter the hospital or to remain under care. In some cities, such as New York or Detroit, enforcement of existing legislation enables the authorities forcibly to admit to the hospital and detain infectious patients who do not provide proper care for themselves at home or who conduct themselves in such a manner that they are a menace to those about them. The large number of patients who leave the Philadelphia General Hospital against advice diminishes to a considerable extent the value of the hospital as a means of protecting the community by isolation of infectious patients.

Because of the frequency of short stay in the hospital, information covering a period of more than ten weeks was available for only seventy-seven patients who received artificial pneumothorax treatment. Treatment of sixteen of these was bilateral. Improvement occurred in 47 per cent of cases in which the results of pneumothorax treatment are here analyzed. There was improvement in 25 per cent of the Negroes and in 62 per cent of the white patients.

The results of treatment depend to a large extent on the type of collapse obtained. In this series of patients with advanced disease only one in five of all patients on whom pneumothorax was attempted obtained an anatomically satisfactory collapse; there was no appreciable difference between the colored and white groups in this respect. Satisfactory results were almost limited to the small number of patients who obtained a good collapse. Improvement occurred in 87 per cent of this group, while of the four fifths having a fair space, a poor space, or no space, less than a third were improved. This was likewise true of the patients who received bilateral pneumothorax, all of the eight patients who improved having a satisfactory collapse. Accordingly, in cases in which the advisability of pneumothorax treatment is questionable, collapse may be attempted. In the event of a good space this treatment should be continued. But, in the absence of a good space, continuation of artificial pneumothorax treatment in cases of advanced disease is of doubtful value. When the space is actually poor, especially if pressure readings are unsatisfactory, continued treatment may be not only useless but actually harmful.

Complications of pneumothorax treatment occur more frequently among patients with advanced tuberculosis. In the group under discussion, 65 per cent had either adherent pleura or adhesions that interfered with a satisfactory collapse. The incidence of other complications, including spontaneous pneumothorax and pleurisy with effusion, is likewise high. Following pneumothorax treatment in the hospital, two patients died of spontaneous pneumothorax and two as the result of heart failure. An additional seventeen patients died in the hospital of progressive disease, a fact illustrating that in spite of pneumothorax treatment advanced lesions are frequently uncontrolled. Since they may nullify the value of treatment, the frequency of progressive disease and the likelihood of complications should be taken into consideration in deciding the advisability of attempting collapse therapy.

With increasing reliance on collapse therapy in the treatment of pulmonary tuberculosis, the proper evaluation of bed rest is frequently not appreciated. In cases of less advanced disease and hopeful prognosis there

is a tendency to allow more activity, while in cases of progressive disease in which the prognosis is hopeless, strict bed rest is frequently enforced, even though the physician is aware that the disease is incurable and will progress to fatal termination in spite of treatment. It would seem more reasonable to reverse this procedure. The patient with the earlier lesion and better prognosis is precisely the one for whom complete bed rest should be urged, since this may be the factor that determines whether or not the disease will be controlled. On the other hand, provided isolation is maintained, strict bed rest need not be enforced on the patient with advanced disease and hopeless prognosis, if he would be more contented with some activity.

It is not questioned that artificial pneumothorax is a very valuable method of treatment in individual cases and that it may be substituted for institutional care in cases of tuberculosis in which sputum can be rendered negative for tubercle bacilli. Its application should be restricted to suitable cases, however, and it should not be used indiscriminately in an attempt to control far advanced disease. This opinion is wholly in agreement with views recently exposed in an editorial² in *THE JOURNAL*. Commenting on the results of collapse therapy in Chicago, the author made it clear that pneumothorax therapy cannot be regarded as "more than a significant aid in the wider problem of the eradication of tuberculosis" and that tuberculosis control remains "largely a matter of early diagnosis and segregation."

CONCLUSIONS

1. The value of a municipal hospital for the isolation and treatment of indigent patients with advanced pulmonary tuberculosis is limited by the fact that many patients remain in the hospital for short periods only and leave against advice.

2. Lack of or failure to enforce legislation enabling authorities to admit and detain infectious patients diminishes to a large extent the value of the municipal hospital in the protection of the community from tuberculosis.

3. Since the number of patients with advanced disease for whom pneumothorax treatment is successful is relatively small, and since approximately two thirds of these remain sputum positive, pneumothorax treatment, although definitely of benefit to some patients, is not a major function of the hospital as far as the protection of the community is concerned.

4. Pneumothorax should not be attempted for patients with advanced disease when the sole reason for its application is that the prognosis is otherwise hopeless. More harm than good may be accomplished in these cases.

5. The good results of pneumothorax treatment are largely confined to those patients obtaining an anatomically satisfactory collapse.

6. Pneumothorax treatment should be attempted in every case in which this form of therapy seems to offer a chance of improvement, but if a satisfactory pneumothorax space cannot be obtained, prompt discontinuation of this form of therapy is usually advisable.

7. Patients with favorable prognosis should have complete bed rest, even though relatively little disease is present but, provided isolation is maintained, strict bed rest need not be enforced in cases of progressive disease in which the prognosis is hopeless.

ALTITUDE AND ARTIFICIAL
PNEUMOTHORAX

C. H. GELLENTHIEN, M.D.

VALMORA, N. M.

Regular established commercial airlines now fly at a constant minimum altitude of 2,000 feet over the passing terrain. To get over the Rocky Mountains they have to rise to at least 15,000 feet. These high altitudes produce definite and prompt physiologic changes which may profoundly affect any patient with artificial pneumothorax.

In the normal person the pleural cavity between the chest wall and the outer sac of the lung is only a potential cavity; that is, the two surfaces are everywhere in close contact with each other and no actual space exists. The reason for this is evident, as in this potential cavity the pressure is normally negative, that is, less than one atmosphere, while the pressure within the lungs is always the pressure of the outer atmosphere. As the interior of the lungs communicates freely with the outside air through the trachea, glottis and other structures, the two surfaces are conjointly held tight against the chest wall at all times by this difference in pressure between the inside and the outside.

The condition resulting from the artificial introduction of air into the pleural cavity, the principle of which is well known, is called pneumothorax. Briefly, the artificial introduction of air into this potential cavity reduces the negative pressure in the cavity, eliminating the normal pressure differential between the two walls, and as there is no longer sufficient difference in pressure between the two sides of the lung sac to hold it out against the chest wall, the lung collapses. If sufficient air is introduced into the pleural cavity thus produced, the lung will collapse completely and will in effect become solid. The degree of collapse is determined by the amount of air introduced, which varies with the degree of collapse indicated and the outer atmospheric pressure. When the pressure in the pleural cavity equals that of the outside atmosphere, the lung is completely collapsed. However, obviously this condition is not stable. The air in the pleural cavity is gradually absorbed by the body, and the lung expands as the absorption takes place. The rate of absorption is not constant, and to maintain as complete a collapse as possible at all times, a fresh supply of air must be introduced at frequent intervals.

Another, and possibly more important, factor which may upset the equilibrium of a perfect collapse is the change in atmospheric pressure resulting from decided changes in altitude when traveling. As the pleural cavity is completely closed to the outside, the air introduced into this cavity must be governed by the simple gas laws as far as changes in pressure and volume are concerned. An increase in atmospheric pressure on the outside of the body, due to a reduction in altitude, acting on this air through the flexible medium of the lung, would compress the air within the lung and reduce its volume; since the pressure within the pleural cavity is affected only by the rate of body absorption, it allows the lung to expand while a new condition of equilibrium is reached. Conversely, a decrease in atmospheric pressure due to an increase in altitude would cause the air in the cavity to expand and the lung to collapse, since the pressure within the pleural cavity would then exceed the decreased atmospheric pressure within the

lung. Atmospheric pressure could be decreased without difficulty until the lung became completely solid. At this point, however, there could be no further expansion of the air without an accompanying increase in pressure above the atmospheric level because the flexibility of the lung has disappeared and the air is enclosed in a semirigid cavity. As the pressure in the pleural cavity acts directly on the heart and the other organs in the mediastinal space, any increase in pressure above the atmospheric level is apt to be critical. Not only may it cause considerable discomfort but, if allowed to go high enough, it may result in serious difficulty and even death, if the heart and other organs are not able to readjust themselves promptly.

The altitude to which one can go without expecting difficulty depends on how near the lung is to being collapsed when one starts out. If considerable time has elapsed since a fresh supply of air was introduced and the body has absorbed considerable air from the cavity, one can go up several thousand feet without difficulty.

To determine just how high one can go without obtaining a positive pressure at any given time after a

The maximum altitude in feet above sea level to which a typical patient may ascend during a ten day period after pneumothorax has been given.

fresh supply of air has been introduced into the pleural cavity, the accompanying chart was developed.

As practically all the factors which affect the maximum safe altitude are different for each individual, a separate chart must be made in each case. In making the chart, the following points must be established:

A. Altitude at which patient has been living and at which last supply of air was added to the pleural cavity.

T. Time interval for replenishing air.

v. Total capacity of pleural cavity in cubic centimeters when lung is completely collapsed.

V. Capacity of pleural cavity in cubic centimeters after absorption has taken place (varies from time to time).

P = Atmospheric pressure in inches of mercury at altitude A. (Standard sea level pressure is 29.92 inches of mercury. Reduce 1 inch for each thousand feet above sea level.)

p. Atmospheric pressure at maximum safe altitude. $p = \frac{PV}{v}$

A_m. Maximum altitude in feet above sea level to which one can go without difficulty (varies from day to day after pneumothorax has been given.)

A_m. (29.92 inches — p) 1,000.

The value v is the total capacity of the pleural cavity when the lung is collapsed.

The value V may be obtained for each consecutive day by substituting the average daily absorption from v for each day after pneumothorax has been given.

As an example of how to make calculations, let us assume that John Jones, who lives at an altitude of 1,000 feet, has a pneumothorax in his left lung. He has 400 cc. of air added to his pleural cavity every ten days. From measurements of his x-ray plate he finds his chest volume to be approximately 4,500 cc. It is assumed that the absorption of the air takes place at a constant rate of 40 cc. a day. In this case the quantities just enumerated would be:

$$A = 1,000 \text{ feet.}$$

$$T = 10 \text{ days.}$$

$$v = 4,500 \text{ cc.}$$

$$V = 4,460 \text{ cc. at end of first day; 4,420 at end of second day, and so on.}$$

$$P = 28.92 \text{ inches of mercury.}$$

The values p and A_M must be calculated as in the following examples:

At end of first day:

$$p = \frac{28.92 (4,460)}{4,500} = 28.66 \text{ inches.}$$

$$A_M = (29.92 - 28.66) 1,000 = 1,260 \text{ feet.}$$

At end of tenth day:

$$p = \frac{28.92 (4,100)}{4,500} = 26.34 \text{ inches.}$$

$$A_M = (29.92 - 26.34) 1,000 = 3,580 \text{ feet.}$$

Calculations for the entire ten day period are shown in the table.

Values at End of Each Day

Days	1	2	3	4	5	6	7	8	9	10
V	4,460	4,420	4,380	4,340	4,300	4,260	4,220	4,180	4,140	4,100
P	28.92	28.92	28.92	28.92	28.92	28.92	28.92	28.92	28.92	28.92
v	4,500	4,500	4,500	4,500	4,500	4,500	4,500	4,500	4,500	4,500
p	28.66	28.40	28.14	27.89	27.63	27.37	27.12	26.86	26.60	26.34
A _M	1,260	1,520	1,780	2,030	2,280	2,550	2,800	3,060	3,320	3,580

These values may be graphed as in the chart, with the altitude as ordinate and the time in days as abscissa.

CONCLUSIONS

1. In pneumothorax the air within the pleural cavity is subject to the ordinary physical laws of the expansion of gas.

2. A knowledge of the application of these laws in individual cases may be valuable in determining the size of injection when changes of altitude are contemplated.

3. The method presented here is based on the measurement of the ordinary 6 foot roentgenogram of the chest combined with known data of altitude, present and contemplated, and the size of the pneumothorax injection.

Valmora Sanatorium.

Organic Acids in Foods.—The organic acids citric, malic, tartaric, oxalic and benzoic are widely distributed in common foods. Less common ones like succinic, isocitric, malonic, salicylic and quinic acids also are found in some foods. The present point of view regarding these acids is that they are not mere waste products of metabolism in either plants or animals but that they play fundamental, though as yet undefined, roles in some of the physiologic processes of the body. Some of the organic acids recognized as typical plant constituents are synthesized in the animal body and, in some instances, both the condition of their formation and their precursors are known.—Smith, Arthur H.: *Nutrition and Dietetics*, chapter I in *The Therapeutics of Internal Medicine*, New York, D. Appleton-Century Company, Inc., 1940.

ASPIRATION PNEUMONITIS

AN OBSTETRIC HAZARD

CHARLES C. HALL, M.D.

OAKLAND, CALIF.

In October 1937 one of my patients entered the Samuel Merritt Hospital in Oakland in labor at term. She was a healthy normal woman in excellent physical condition, looking forward eagerly and happily to the birth of her first child. She had an ample pelvis, the presentation was normal, and she was assured with confidence that before long her dreams would be realized.

Dilatation progressed normally, and eventually the head was bulging the perineum. The patient was given gas anesthesia for a low forceps extraction. During the course of the anesthesia she gagged and vomited and became very cyanotic. Respiration ceased. Artificial respiration was used for a few seconds and she began to breathe again. Soon her color became normal and it remained so throughout the rest of the delivery and repair. She was returned to her room in good condition, with normal pulse and respiration and no cough.

Thirteen days later she was dead, and the sorrowing husband took the baby they had both wanted so much back to an empty house.

This tragic occurrence caused me to embark on a search for similar cases to see what errors of commission or omission, if any, made such tragedies possible. A careful search of all the medical literature failed to yield a single detailed report of a similar case. The textbooks on anesthesia, as well as numerous articles, mention it as a possibility, but no case reports could be found. Not long afterward, however, I was called in consultation to see a similar case in another local hospital, and inquiry among friends in the East Bay, in San Francisco and in Los Angeles has brought reports of fourteen similar cases. How many more there have been cannot be known. The majority are not fatal and are not reported.

This article constitutes a review of this group of cases, including my own, to see whether any conclusions can be drawn from them. The physicians of these patients gave me permission to use this material.

REPORT OF CASES

CASE 1.—A primipara aged 33 entered the hospital at 1:30 a. m. in the early first stage of labor at term. Rectal examination showed no dilatation. A mixture of scopolamine, morphine and cactine (H. M. C. 1) was given at 3 a. m. so that the patient could secure some sleep. The following forenoon the pains continued to be weak and irregular. At 1:30 p. m. rectal examination showed only 1 cm. of dilatation and it was decided to try to stimulate the contractions with small doses of solution of posterior pituitary, after preliminary sedation. At 2 p. m. she was given sodium allyl (1-methylbutylbarbiturate) $7\frac{1}{2}$ grains (0.5 Gm.) by mouth and scopolamine $\frac{3}{100}$ grain (0.0004 Gm.) by hypodermic. At 2:15 p. m. 2 minims (0.12 cc.) of solution of posterior pituitary was given by hypodermic. This gave contractions which remained strong, so that no further solution of posterior pituitary was necessary. Much motor excitement developed and the patient became noisy so that morphine sulfate one-eighth grain (0.008 Gm.) was given at 3:30 p. m. By 6:30 p. m. dilatation was complete, with the head low in the midpelvis. The patient was taken to the delivery room and an attempt was made to get her to push. The head soon came in sight and it was decided to deliver the child with low forceps. Gas anesthesia was started by a trained and skilful nurse anesthetist. About four minutes

Read before the annual meeting of the California Medical Association at Del Monte, May 3, 1937.

after the start of the gas anesthesia the patient gagged and vomited. Respiration ceased and she became very cyanotic. Artificial respiration was resorted to and she soon started breathing again. Her color soon became and remained good. There was no coughing.

The baby was delivered in good condition. The patient was returned to bed at 7:30 p. m. Her pulse rate was 84 and respiratory rate 26. She was still asleep and her breathing was stertorous, but her color was good. A special nurse remained with her.

By 9:30 p. m. she was cyanotic and gasping for air. Atropine $\frac{1}{500}$ grain was given and inhalation of oxygen and carbon dioxide was started. Examination of her chest showed coarse bubbling rales throughout. Dr. Hobart Rogers, an internist, was called in consultation. Four hundred cc. of 25 per cent sucrose was given intravenously and another $\frac{1}{500}$ grain of atropine. The patient was placed in an oxygen tent, and one ampule of metrazol was ordered given every four hours.

The following morning an x-ray study of the chest was made. The radiologist reported that there was very extensive coarse mottling extending throughout the right lung, most pronounced adjacent to the hilus and gradually diminishing as the periphery of the chest was approached. The shadows were large, soft, indistinct densities following no special distribution; however, there seemed to be more pathologic change in the middle lobe. In the left side there was similar but not quite as extensive mottling, which appeared to be distributed principally in the lower portion of the upper lobe.

The blood count is reported in table 2. The remarkable thing about it was the extremely high percentage of nonfilamented forms. Throughout the day the respiratory rate even in the oxygen tent remained between 40 and 50 and the pulse rate between 110 and 140, though the temperature averaged only about 100 F. (ranging from 102 at 8 a. m. to 98.8 at 11 p. m.). One thousand cc. of 5 per cent dextrose was given during this day and also a transfusion of 680 cc. of citrated blood, it being thought that increasing the number of circulating red cells would aid the blood in its oxygen carrying capacity. The patient coughed but rarely and then raised small amounts of thick rusty sputum, which showed a streptococcus in a smear.

The patient remained continuously in an oxygen tent and was kept alive by this means for thirteen days with but little change in her clinical condition. The oxygen concentration in the tent had to be maintained at between 50 and 60 per cent with from 7 to 10 liters per minute running. Even in this atmosphere her respiratory rate was constantly between 50 and 35 per minute. Her pulse rate remained fairly stationary between 120 and 130. Her temperature oscillated between 99.6 and 101 F. except at the very end.

TABLE 1.—Pulse and Respiration in Case 1

Time, P. M.	Pulse Rate	Respiratory Rate
8	92	26
8:30	100	30
9	120	32
9:30	130	34

X-ray examinations of her chest made on four occasions showed a progressive increase in the areas of density. Blood counts were made almost daily. A second transfusion of 500 cc. was given on the eleventh day. Metrazol was given by hypodermic every four hours.

The patient died thirteen days after delivery. A partial autopsy showed both lungs full of a diffuse wet consolidation with air present only at the extreme apexes.

CASE 2.—A primipara was admitted to the hospital in active labor. Fifty minutes after admission she was given pentobarbital sodium 3 grains (0.2 Gm.), and one hour later paraldehyde by rectum. The paraldehyde was not retained and so was given again twenty-seven minutes after the first instillation. Forty-five minutes after the second instillation of paraldehyde the patient, who was having pains, was taken to the delivery room for gas anesthesia. The head came down to

the perineum and after forty-seven minutes of gas anesthesia the physician delivered the baby with low forceps. The patient vomited and became cyanotic. Her pulse rate shot up to 156. She was given oxygen inhalations, with nikethamide (coramine) and solution of epinephrine hydrochloride by hypodermic, and soon her color improved. She coughed considerably for several days. After the first few hours her pulse rate settled down to normal. Her respiratory rate was never over 24. She was treated with intermittent inhalations of carbon dioxide and oxygen. A white blood cell count on the fifth day after

delivery was 21,200 with 88 per cent polymorphonuclears and 12 stab cells. No chest roentgenogram was made. She left the hospital on the tenth day in good condition.

CASE 3.—A primipara aged 30, on whom the physician decided to do a cesarean section because of failure of the head to engage after seven and one-half hours of labor, had no analgesia until this decision was made, when she was given $1\frac{1}{2}$ grains (0.1 Gm.) of pentobarbital sodium by mouth and 1 grain (0.06 Gm.) of codeine by hypodermic. Gas anesthesia was started thirty-seven minutes after the medication. While the physicians were inserting sutures, forty-eight minutes after the anesthetic had been started, the patient vomited a large quantity of undigested food. She became cyanotic and remained so for about four hours. She coughed much and during the next few hours "raised considerable dark material similar to what she had previously vomited." The next day she had a slight cough, with sputum described as rusty. She was treated with frequent inhalations of carbon dioxide and oxygen for seven days. Her convalescence was uneventful. No blood counts or x-ray studies were made.

CASE 4.—A primipara entered the hospital apparently just beginning labor. She was given sodium allyl as shown in table 3. She thus received a total of $10\frac{1}{2}$ grains (0.7 Gm.) over a period of ten hours. With the coming of morning the physician stopped sodium allyl medication. Dilatation was progressing very slowly and he decided to accelerate labor. During the day the patient was given 10 minims (0.6 cc.) of solution of posterior pituitary in six doses. During this time the only analgesia given was $\frac{1}{6}$ grain (0.01 Gm.) of morphine at 3:30 p. m. By 7 p. m. dilatation was reported complete. At 9 p. m. the physician decided to deliver the baby with low forceps. Open drop ether was used to put the patient to sleep. Forceps were being placed on the head when the patient vomited a large amount of what was described as "coffee ground" vomitus. She inhaled some of it and ceased breathing. She was given nikethamide twice. When respirations began oxygen was given, but the patient's condition was so poor that the physician thought it best to discontinue attempts at delivery for a time. The patient was left lying on the delivery table with her head lowered; the anesthetist continued to give oxygen and carbon dioxide for two or three hours. The shocklike condition apparently caused absolute loss of tonicity in the uterine muscle. This, combined with the fact that the patient was lying with her head much lowered, caused the baby's head to fall back entirely out of the pelvis. I saw this patient in consultation about four hours after the incident. She was still dusky; her respiration was rapid and her pulse rate 140. The presenting part was far above the pelvic brim. It was thought

best to ignore the pregnancy and treat the shock for the time being. The patient was put back to bed. After some hours, uterine tone returned; the head reentered the pelvis and came down to the perineum with right occipitotransverse presentation. There it remained with the sagittal suture transverse for two hours, and it was decided that forceps must be used to rotate it and deliver the baby. The patient was given a spinal anesthetic and delivery was easily effected.

A roentgenogram of the chest taken fourteen hours after aspiration showed an area of haziness and increased density in the lower lobe of the left lung.

A white blood count taken twelve hours after the aspiration showed 22,400 cells; with 95 per cent polymorphonuclears and 45 stab cells.

During the next few days there developed symptoms suggestive of a moderately severe bronchopneumonia. The patient's

TABLE 3.—Administration of Sodium Allyl in Case 4

1½.....	Midnight
3.....	2 a. m.
1½.....	7 a. m.

maximum temperature three days after delivery was 102.6 F. By the eighth day following delivery her temperature was normal and she went home in good condition.

CASE 5.—A woman entered the hospital with pains occurring every five minutes. Five hours after admission, when her cervix was reported as dilated 4 fingerbreadths, she was given pentobarbital sodium 3 grains and one hour later scopolamine ½ grain. She was taken to the delivery room with the head showing at 1:30 a. m., five and a half hours after administration of pentobarbital sodium and four and a half hours after scopolamine. Vaginal examination showed the head to be in direct posterior position, and the physician decided to deliver it in this position with forceps. The patient was anesthetized with gas. During the delivery she began to vomit "black coffee ground material" and it was felt at the time that she had probably aspirated some of the vomitus. Her pulse rate rose to 156 and respiratory rate to 40. She was given carbon dioxide-oxygen mixture and nikethamide by hypodermic. Gradually her condition improved, although six hours later her pulse rate was still 130 and respiratory rate 24. A persistent cough developed. She was given carbon dioxide-oxygen mixture for five minutes every two hours for forty-eight hours, after which time treatment consisted of diathermy applied to her chest and administration of elixir of terpin hydrate. She did not at any time have clinical symptoms of pneumonia. No roentgenogram was taken and no white count was done.

CASE 6.—A woman was admitted to the hospital with mild pains and a 4 cm. dilatation. About one hour after admission she was given pentobarbital sodium 3 grains, and twenty minutes later scopolamine ½ grain (0.6 mg.). The same dose of scopolamine was repeated in another twenty minutes and again two hours later. The patient was delivered with low forceps under gas anesthesia eighteen minutes after her third hypodermic of scopolamine. While the physician was repairing an episiotomy the patient vomited and became cyanotic. Her head was lowered and she was given carbon dioxide-oxygen mixture and oxygen (90:10); this was continued for one and a half minutes every twenty minutes for the next thirty-six hours. She coughed up considerable vomitus. X-ray study of her chest on the day following delivery showed no involvement of her lungs. The white count the day following delivery showed 17,100 cells, 82 polymorphonuclears and 30 stab cells. Four days later it was 13,500 cells, with 80 polymorphonuclears and 13 stab cells.

CASE 7.—A primipara aged 26 began having pains at 1 a. m.; labor progressed rapidly. She was given scopolamine ½ grain (0.3 mg.) at 3:25 a. m. and pantopon ½ grain (0.02 Gm.) at 3:50 p. m. Labor progressed steadily with severe pains which did not respond well to the analgesia. After

complete dilatation, the head being on the perineum, the patient was given gas-ether anesthesia and the baby was delivered by outlet forceps. As she was coming out of the anesthesia after delivery of the baby's head the patient vomited and aspirated some of the vomitus. Respiration ceased; the heart continuing to beat slowly but strongly. Artificial respiration was used. One cc. of nikethamide was administered intravenously and 1 cc. of solution of epinephrine hydrochloride was injected into the cardiac muscle. Gradually the heart became weaker and death ensued.

Autopsy showed both lungs collapsed and the bronchi of each lung filled with dark colored contents, apparently spinach or some other dark food.

CASE 8.—A woman entered the hospital at 2:20 p. m. saying that she had been having pains for ten hours. The contractions were very weak and it was questioned whether she was in true labor. About 7 p. m., however, pains became strong and definite. At 8 o'clock she was given scopolamine ½ grain. At 9 o'clock this medication was repeated with addition of pentobarbital sodium 3 grains (0.18 Gm.). Ether was also given rectally at this time but was not retained. At 9:30 the patient was taken to the delivery room and administration of gas and oxygen was started, the anesthesia being given by a physician specializing in anesthesiology. The membranes were ruptured artificially and the baby was delivered with low forceps at 10:07 p. m. The patient vomited during delivery. After the repair, her stomach was washed out until clear. Carbon dioxide-oxygen mixture was given for ten minutes every hour until the following morning. On the following day the patient stated that she felt fine. The temperature was normal. However, the respiratory rate was 32; she had an occasional thick cough, and there were scattered rales over the lower lobes of both lungs posteriorly, especially on the left. Two days later the cough was somewhat worse, with pink tinged expectoration. The temperature was only 99.2 F. but examination of the chest revealed increased voice sounds with coarse and fine rales at the base of the left lung. The patient was discharged fourteen days after delivery with normal temperature and respiration. She still had some cough. She was hoarse for at least six weeks and could not smoke comfortably for some months, although previously she had used about one pack of cigarettes a day.

CASE 9.—A woman entered the hospital after having had pains for twelve hours at home. The cervix was dilated from 5 to 6 cm. on admission; pains occurred every five minutes, lasting from thirty-five to forty seconds. The baby was in breech presentation. After routine preparation she was given

TABLE 4.—Blood Count in Case 9

Days Post Partum	White Cell Count	Polymorphonuclears	Non-segmented Cells
2	34,900	95	19
5	23,700	87	45
9	13,400	67	9

pentobarbital sodium 4½ grains (0.3 Gm.). The baby was delivered about three and one-half hours later. During delivery the mother vomited a quantity of yellow liquid and probably aspirated some of it. She began to cough immediately and for the next few days her cough was very distressing. Two hours after delivery it was noted that she was raising "pink frothy material"; on the following morning considerable bloody mucus was being expectorated. The respiratory rate eight hours after delivery was 30 and the pulse rate 140. Twenty-four hours after delivery the pulse rate was still 140 and the respiratory rate 32. Her face and hands were very cyanotic, and nasal administration of oxygen was started. This was kept up continuously for the next three days, after which it was discontinued, although the respiratory rate was still 32 and the pulse rate 110. This patient remained in the hospital for eighteen days. Her temperature during most of this time was about 100 F. It never went over 101 and was still going to 99.6 on the eighteenth day post partum. The pulse rate never fell below 100 until the eleventh day post partum. She was seen in con-

sultation by an internist, Dr. Philip Pierson, who found scattered crepitant rattling and wheezing rales over the lower and middle lobes of the left lung. Roentgenograms of the chest made on the eighth and the fourteenth day post partum were reported as showing evidence of diffuse bronchopneumonia.

Sputum examination six days post partum showed a moderate number of pus cells within a few gram-positive diplococci. On culture, the sputum revealed *Streptococcus viridans* and a non-hemolytic streptococcus.

CASE 10.—A primipara aged 21 was delivered by outlet forceps after twenty-seven hours of labor. There is no record of the analgesia that was used in this case. The anesthetic for delivery was gas-ether, given by a nurse anesthetist. The patient vomited just prior to delivery and the physician states that there was a large amount of undigested food. This patient's chart showed no marked effect on her temperature, pulse or respiration until about twenty-four hours after delivery. At about that time the temperature began to rise steadily, reaching a peak of 103.4 F. on the fourth day post partum (the highest temperature recorded in this series); thereafter it gradually fell to normal. Her pulse rate rose to 120 about twenty-four hours after delivery and remained between that point and 150 during the next three days. Her respiratory rate was not noted as elevated until about forty-eight hours after delivery, but it reached 46 on the fourth day post partum, at the time of her greatest fever. She complained of shortness of breath and irritation in the trachea on forced inspiration. X-ray study of her chest on the fourth day post partum showed some density in the lower lobe of the left lung behind the heart shadow, very suggestive of a small amount of pneumonitis. This patient left the hospital on the eleventh day, still having a low grade afternoon fever, which the physician attributed to her chest condition.

CASE 11.—A primipara aged 32 had labor pains at 5 p. m. just after eating a large bowl of vegetable soup. The pains were severe and close together. The progress of labor was rapid. By 9:20 p. m. the cervix was fully dilated. When the head came down to the perineum a low forceps delivery was done. The patient took the anesthetic poorly and vomited a large amount of acid fluid, probably the soup. Although the anesthetic was given by the chief anesthetist of the hospital, aspiration was considerable. There was moderate laceration of the perineum, which was repaired immediately. One hour post partum the patient was not in great distress but could not sleep because of headache and cough.

At 8 o'clock the following morning the patient was cyanotic and coughing. Beginning pneumonia was diagnosed by a well recognized internist. By 5:30 p. m. cyanosis was extreme. The respiratory rate was from 50 to 55 per minute and the pulse rate from 128 to 148. Examination showed that the lungs were full of fluid. Considerable frothy blood stained fluid was constantly being expectorated. Atropine $\frac{1}{400}$ grain was given and the dose was repeated without apparent effect. A venesection of 400 cc. was done without improving the patient's condition, which grew rapidly worse. She died at 8:35 p. m., about twenty-two and one-half hours after the aspiration.

CASE 12.—A woman decided during dinner that she would like to have her baby that evening. After dinner she went to the hospital, where the baby was delivered by classic cesarean section. She was at term but not in labor. Gas-oxygen anesthesia was used. The patient started vomiting shortly after the baby was delivered. Respirations ceased; although her heart continued to beat for some time, breathing could not be started. There was no autopsy.

CASE 13.—A patient was delivered by cesarean section after a twenty hour test of labor. During this twenty hours she received 15 grains (1 Gm.) of pentobarbital sodium (6 grains [0.4 Gm.], 3 grains, [0.2 Gm.], 3 grains, 3 grains) and $\frac{1}{200}$ grain (1.2 mg.) of scopolamine ($\frac{1}{400}$ grain with each dose of pentobarbital sodium). There was a face presentation. When the decision to do a cesarean section was made an additional $\frac{1}{150}$ grain of scopolamine was given. The anesthesia used for surgical intervention was cyclopropane; the anesthetist was a trained and skilful physician. The vomiting occurred just after skin closure. The patient's head was slightly lower than the rest of her body at this time. The only immediate treatment

consisted of turning the head to one side and wiping the face. There was no immediate reaction. The temperature at the time of operation was 37.5 C. (99.5 F.) and five hours later rose to 38.5 C. (101.3 F.). After pursuing an irregular course, it reached 40.4 C. (104.7 F.) on the fourth postoperative day. From this point the trend was irregularly downward, the value reaching normal, to remain there, on the thirteenth postoperative day. The pulse rate rose from 90 at the time of operation to 132 five hours later, reached its high point of 140 in fifteen hours and thereafter ranged irregularly downward, becoming normal on the nineteenth day. The respiratory rate was 18 before operation, rose in eight hours to 24, ranged between 20 and 24 during the next twenty-four hours and reached 32 during the succeeding twenty-four hours. At the end of the third postoperative day it reached 48. It varied between 32 and 48 during the next forty-eight hours, after which it varied between 20 and 28. The rate came down to an essentially normal level on the eighth postoperative day.

X-ray study on the fifth postoperative day showed some consolidation in the lower lobes of both lungs, more on the right side. On the eleventh postoperative day x-ray examination still showed some consolidation, though less, with a high diaphragm; on the eighteenth postoperative day both lungs looked clear.

Blood culture on the fourth postoperative day yielded no growth.

Sputum examination on the fourth day after operation revealed large numbers of *Staphylococcus aureus* and moderate numbers of *Streptococcus viridans* with a few nonhemolytic streptococci. A white mouse which was inoculated was normal after seventy-two hours. The Neufeld test was negative.

CASE 14.—A primipara aged 22 was in perfect physical condition. Labor started spontaneously. The first stage lasted twelve hours. There is no note on the record as to what analgesia was used. With the head on the perineum the patient was taken to the delivery room for prophylactic forceps. She had had no solid food for twenty-two hours. Gas and oxygen anesthesia was given by an intern with limited anesthetic training. About two minutes after the induction of anesthesia the patient began to vomit and became cyanotic. Anesthesia was stopped and the patient turned on her side to aid removal of vomitus. Cyanosis increased and respiration ceased. Suction was used to remove particles of undigested food, which must have been eaten at least twenty-two hours previously. All efforts at artificial respiration, including a pulmotor, failed, and heart action ceased. No forceps were applied until the mother's pulse ceased. Efforts to resuscitate the baby, delivered post mortem, failed. There was no autopsy.

CASE 15.—This case represents the only aspiration in the series not occurring at the time of delivery. A woman aged 35 entered the hospital one afternoon for an operation to remove what turned out to be a dermoid cyst of the ovary. She was operated on the following morning after careful preoperative preparation. The anesthetic was being given by a trained nurse anesthetist. The abdomen was opened through a midline incision. While packs were being placed in the abdominal cavity the patient vomited what looked like orange juice. Directly thereafter pinkish foam began to issue from her nose and mouth, the color soon changing to dark brown.

The anesthetic was stopped and her mouth was cleared. When she seemed in good condition the anesthetic was resumed and the operation proceeded. About forty-five minutes later, when the surgeon was about ready to close the wound, the patient became cyanotic; her pulse was rapid and irregular, and her blood pressure dropped to 60 systolic. A stomach tube was then passed, and more orange juice and gastric secretion were obtained. Atropine $\frac{1}{15}$ grain (0.0008 Gm.), and 1 cc. of a solution of epinephrine hydrochloride were given by hypodermic, and 60 cc. of 50 per cent dextrose was given intravenously. While the surgeon was closing the wound the patient ceased breathing several times. She was given carbon dioxide and oxygen and eventually was returned to bed in fair condition. Inhalations of carbon dioxide and oxygen were kept up for five minutes every four hours for the next thirty-six hours. There developed a troublesome cough, which was treated with codeine and steam inhalations. The pulse varied between 100

and 120 for the next five days. Five days after operation there was dulness over the entire base of the right lung. The white blood cell count was 8,750 with 71 per cent polymorphonuclears. The patient was raising much sputum containing many elastic fibers, a few gram-positive cocci and occasional red blood cells. On the seventh day she was still coughing with violent paroxysms and raising thick purulent material. Her respiratory rate

was 20 and her pulse rate 100; her white cell count was 12,600 with 72 per cent polymorphonuclears. A roentgenogram taken this day showed the picture of bronchopneumonia on the right; the left lung was clear. She left the hospital in good condition on the eighteenth day.

COMMENT

From a study of this series of cases several things become apparent:

1. Aspiration pneumonia is not a rare condition. These cases were collected merely by making inquiry among a circle of medical acquaintances, twelve of them occurring within the last two years. As to how many other cases there may have been one can only speculate.

2. The condition is serious. In these fifteen cases there were five deaths, while several of the other patients required prolonged hospitalization.

3. There are two types of cases: those in which the material aspirated is of a solid nature and those in which it is fluid. In the first group, death may result rapidly from mechanical obstruction of the air passages or it may be due to the same type of shock which causes sudden death in cases of arterial embolism, even when the fraction of the total lung tissue involved is relatively small. When the aspirated material is of a fluid nature it seems to set up a chemical pneumonia. The x-ray picture may be that of bronchopneumonia, but there are clinical criteria which are different; viz., the temperature reaction is not so high; cyanosis is more marked; the pulse and respiration are apt to be more rapid; the sputum is more pronounced, and the bacteria are apt to be secondary invaders. Possibly the chemical reaction creates an environment unfavorable to bacterial

growth. Possibly the character of the fluid aspirated is of little importance; I feel that the reaction in lung tissue is set up by certain fractions of the gastric juice itself and that whether this juice is mixed with soup or orange juice, milk, or water may make little difference. Clinically the picture is different from that of bronchopneumonia.

4. Fourteen of the fifteen women were in the act of parturition. Three of these were being delivered by cesarean section; one had a breech extraction, all the rest being delivered by low forceps. Is aspiration pneumonia primarily an obstetric complication and if so, why? Is there some factor of pressure on the pelvic floor which makes women especially prone to vomit and inhale deeply, or does this complication occur just as frequently in the practice of general surgery? It has been suggested that the surgical patient is apt to be more carefully prepared for anesthesia than a woman in labor. During the World War I gave many anesthetics in an evacuation hospital in France where pre-operative preparation was nil. I never saw or heard of a case of aspiration pneumonia, but I have made no study of the statistics in the Surgeon General's Office.

5. Does the type or amount of premedication, the analgesia used during labor, have any effect on this condition? Table 5 has been prepared to study this factor.

A specialist in nose and throat work who makes frequent use of the bronchoscope and esophagoscope has informed me that he does not believe it would be possible to give enough barbiturate to abolish the gag reflex.

6. Is the blame for aspiration pneumonia to be placed on the anesthetist? I do not believe it is, although, if the anesthetist is keenly alert, the amount aspirated may be reduced to a minimum.

The anesthetist and type of anesthesia in the cases here reported are indicated in table 6.

Whether anything can be done to prevent this unfortunate complication I am not prepared to say. Probably women in labor should not be given much to eat. If there were no solid material in the stomach, the chance of aspiration of chunks of food which might mechanically obstruct the air passages would be

TABLE 6.—*Type of Anesthesia*

reduced. But the stomach at this time is often slow in emptying itself, and the material regurgitated may have been eaten hours before the onset of labor. Furthermore, several of these patients vomited only fluid; and if the hypothesis is correct that the chemical reaction in lung tissue is set up by some factor in the digestive juices themselves, the presence or absence of food diluting those juices might make little difference.

Certainly every delivery room ought to be equipped with an efficient suction apparatus kept constantly ready

for instant use. Possibly anesthetists should not be permitted to fasten the gas mask on the patient's head, as one sometimes sees them do, since its removal may cause the loss of precious seconds if it becomes filled with vomitus. Possibly all delivery tables should be so constructed that the patient's head could be promptly lowered should vomiting occur, to facilitate escape of the vomited material; and yet in one case (case 13) the head was lowered at the time aspiration occurred.

SUMMARY

Of a series of fifteen cases of aspiration pneumonitis, five resulted in death; fourteen of them concerned women who were being delivered of a baby. A study of these cases fails to disclose any factor which was present in enough instances to make it seem a predisposing cause. Some measures may help prevent it. The treatment at present is purely symptomatic.

In reporting this series of cases I hope to arouse the interest of others who may help solve the question as to how frequently this unfortunate accident occurs in general surgery or whether it is chiefly an obstetric hazard.

411 Thirtieth Street.

THE INCIDENCE AND MECHANISM
OF BILATERAL PLEURAL
EFFUSIONS

BURGESS GORDON, M.D.

PHILADELPHIA

The simultaneous occurrence of bilateral pleural effusions is rare except in cardiorenal disease and as a direct complication of bilateral artificial pneumothorax used in the treatment of pulmonary tuberculosis. In comparison there is a relatively high incidence of unilateral tuberculous effusions occurring spontaneously or in connection with artificial pneumothorax, as shown in a study of 700 cases studied at the Department for Diseases of the Chest of the Jefferson Hospital and of an additional series from one service of the White Haven Sanatorium. According to the past histories there had been 108 pleural effusions and following entry 151.

Concerning the group of effusions observed during hospitalization, ninety-two were definite complications of artificial pneumothorax, of which fourteen cases were bilateral, the fluid having developed somewhat in relation to the progression of the pneumothoraces; in three cases of bilateral pneumothorax the fluid was limited entirely to one pleural cavity. Five patients with effusions of one pleural cavity following pneumothorax had subsequent development of fluid on the opposite side but only after the primary collection had disappeared. Similar conditions were noted by Charr¹ in a series of 100 tuberculous patients treated with unilateral artificial pneumothorax; there was no instance of fluid occurring simultaneously in the opposite pleural cavity. A case studied by Theodos² at the Sea View Hospital should be mentioned: For several months a pleural effusion had been present on one side and finally as spontaneous absorption occurred an effusion appeared

in the opposite pleural cavity and subsequently ascites; x-ray study of the spine showed early Pott's disease; the sputum was negative for tubercle bacilli. It was the impression in this case that the second pleural effusion was due to hematogenous tuberculosis. These figures illustrate the relative high incidence of pleural effusions in pulmonary tuberculosis, especially as complications of the artificial pneumothorax; likewise they indicate that effusions rarely occur simultaneously in the opposite or untreated pleural cavity. The data serve as a basis for considering the mechanism of bilateral collections in certain cases of unilateral pulmonary collapse in which reexpansion of the lung has been attempted, the subject of the present paper.

During the past two years four patients have been discovered with moderately advanced pulmonary tuberculosis manifesting unusual developments of pleural fluid. Three patients had been receiving artificial pneumothorax treatments on the right side; the fourth was treated on the left side. Collapse of the lung was inadequate, and it was decided to allow reexpansion so that thoracoplasty or some other form of compression therapy could be tried. After several weeks of conservative treatment without any noticeable change in the contour of the lung, forceful intrapleural suction was tried. With each attempt there was severe pain in the chest with weakness and marked dyspnea, and subsequently fluid developed in the opposite pleural cavity. In the fourth case, with marked retraction of the lung on the pneumothorax side due to apical adhesions and fibrosis, suction was employed less strenuously but severe reactions also occurred. Within about twenty-four hours x-ray examination showed a spontaneous pneumothorax and pulmonary emphysema and subsequently the gradual development of pleural fluid. The fifth patient was a woman 32 years of age who had received unilateral artificial pneumothorax treatments empirically on the left side for the persistent formation of pleural fluid of unknown etiology.³ After about two years of unsuccessful control pneumothorax was discontinued. The lung failed to reexpand and there was no essential retardation of the fluid; then reexpansion of the lung was attempted by means of pleural suction. With each induction of negative intrapleural pressures (—15 to —22) there was severe pain in the chest with extreme dyspnea, displacement of the heart and herniation of the mediastinum toward the affected side; after the third attempt a transudate, which later became an exudate, suddenly developed on the opposite side. Dyspnea continued until the pleural pressures were reduced and equalized on the two sides. Subsequently the condition was proved to be cancer of the pleura, metastasis having originated from a new-growth of the ovary.

The remarkably low incidence of bilateral pleural collections of fluid occurring simultaneously except in bilateral pneumothorax has suggested the possibility that some mechanical factor is responsible, perhaps at first in disturbing the adhesive tension of the pleura and later in causing a rupture of a pleural tubercle leading in turn to spontaneous pneumothorax with its irritating and infecting influences on the pleura. The groundwork for such pleural complications is shown grossly in thoracoscopic studies of pneumothorax cases by Alexander,⁴ Willauer⁵ and others. They have

repeatedly found tubercles of the pleura in all stages of progression and reaction. In not a few instances the formations are greatly increased at the base of adhesions, illustrating the traumatizing influences of cough and of forceful respirations. Thus it would seem that in almost every tuberculous lung with subpleural tubercles there are potentialities for greatly increased pulmonary disease and accordingly the complications of spontaneous pneumothorax and pleural fluid. Likewise any complication of the pleural cavity will be more or less continuously aggravated by reason of the fact that lymphatic drainage from the pleural portion of the lung is directed toward the pleura.

Evidently the exudative pleuritides are more common with than without pneumothorax, and inflammation may develop and extend rapidly in loose tissue and on the free pleural surfaces. Conversely, while the pleurae continue in normal apposition any tuberculous lesion will tend to develop in the form of local granuloma or as a small exudate which is quickly localized. Furthermore, with the pleurae in contact the absorption of exudates will be encouraged by the normal respiratory movements. This pathologic and physiologic relationship is illustrated in Charr's¹ cases in which autopsy was performed, openings being found in the anterior surfaces of the lungs, in the center of large and acutely caseous tubercles, measuring approximately 1.5 cm. in diameter. The visceral pleura covering the caseous nodules, either ruptured or intact, was thin and transparent; when the air was pumped into the main bronchi the intact visceral pleura covering these caseous nodules ballooned out remarkably. While the caseous nodules were numerous on the anterior surface of the lungs, the posterior parts showed marked congestion with areas of pneumonia but without any definite adhesion of the adjacent parietal pleura, thus indicating a fulminating form of tuberculosis. In seven other cases the perforations occurred in the axillary region of the lungs, about midway between the apex and the lower border of the upper lobe, and there was no indication of any perforation through caseous tubercles. Furthermore, there was much pleural thickening about the ruptured areas; the pulmonary tuberculosis was chronic and proliferative. These cases illustrate the possibilities and dangers of pleural complications, e. g. pneumothorax and fluid. It is quite conceivable that the rupture of tubercles and tearing of adhesions are immediately responsible for the intrapleural developments.

According to the present consideration the normal apposition of the pleural surfaces with restricted thoracic movements and undisturbed pulmonary and mediastinal structures is a factor in the prevention of spontaneous pneumothorax and pleural fluid. There is a good deal of discussion as to whether or not a negative intrapleural pressure exists with the pleural surfaces in normal apposition, i. e. without the induction of artificial pneumothorax. Brauer⁶ insists that negative intrapleural pressure is essentially a manifestation of pneumothorax and that the physical force of cohesion between the pleural leaves is sufficient to balance the elastic retraction of the lung. In any event the lung almost fills the thoracic cage, which promotes a mechanical contact of the pleura. The important point as far as pneumothorax is concerned in its relation to the development of pleural fluid is not so much the absence

of negative intrapleural pressure as the loss of pleural apposition throughout. Concerning the effects of fluid in one pleural cavity on the development of fluid in the opposite pleural cavity there appears to be no influence except as to prevention. Evidently the pleural surfaces of the expanded lung on the side opposite the effusion will be opposed with even greater security than normally by reason of the compressive action of the displaced mediastinum and lung. Conversely, the forceful traction or expansion of the collapsed lung as induced by a high negative intrapleural pressure will shift the mediastinum and stretch the opposite lung, thus separating its hitherto opposed pleural surfaces. The events are these: Air and fluid will pass spontaneously or be sucked into the pleural cavity.

There is the possibility that some mechanism other than separation of the pleura with spontaneous pneumothorax may be responsible for the development of pleural fluid. Heart failure, hypostatic congestion and pressure on the azygos veins should be considered. In the present study there was no evidence of disturbed circulation, and the manifestations were relieved promptly with the adjustment of the intrapleural pressure. While displacement may have caused pressure effects on the azygos veins, the shifting was much less marked than is seen in a considerable number of cases of pneumothorax and pleural effusion in which the opposite pleural cavity is not disturbed. On the other hand the transudate which preceded the exudate in the carcinomatous case suggests that blood was sucked first from the fine capillaries into the newly created pleural space. Likewise the occurrence of pulmonary rales and a friction rub in association with pain, dyspnea and the x-ray evidence of mediastinal herniation just prior to the development of fluid emphasize the possibility that "suction" was an important factor.

The immediate symptoms noted during attempts to reexpand the contracted lung may be related to separation or pulling of the pleurae, wrenching or distortion of the mediastinal structures and the interference with pulmonary ventilation, the former two causing thoracic pain, the latter favoring dyspnea. Shortness of breath may be attributed to two factors: Decrease of the vital capacity due to the bilateral pulmonary compression and, perhaps more directly, the gradual bilateral rise of intrapleural pressures, the latter becoming less and less negative—that is, tending to become positive, owing to the proportionate increase of fluid. Since cohesion of the pleural surfaces is lost with the onset of fluid there is no suction to counterbalance the normal elastic retraction of the lungs and thus the respiratory movements proceed in a restricted manner. Instead of the pressure becoming more and more negative as the thorax expands normally, which would cause an inspiratory rush of air, the pleural pressure increases to a point at which it becomes so positive that the inspiratory passage of air is impossible. This was proved repeatedly with the carcinomatous patient, from whom various amounts of fluid were removed, after which the intrapleural pressure was changed alternately by withdrawing or introducing air, the purpose being to cause the variation to range between subatmospheric and atmospheric levels.

CONCLUSIONS

1. A series of 259 cases of pleural effusion was studied to determine the frequency of spontaneous, simultaneous bilateral collections of fluid; there was no instance of this particular development.

6. Brauer, Ludolph, and Spengler, Lucius: Die operative Behandlung der Tuberkulose, in *Handbuch der Lungentuberkulose*, ed. 2, Leipzig, Johann Ambrosius Barth, 1919, vol. 3, p. 170.

2. Simultaneous bilateral effusions were noted in four cases of pulmonary tuberculosis and in one case of pleural new growth in which intrapleural suction had been substituted for unilateral artificial pneumothorax on the originally treated side.

3. The present study suggests that the occurrence of fluid in the opposite, or untreated, pleural cavity in cases of artificial pneumothorax is closely related to intrapleural suction used to reexpand the contracted lung.

4. The mechanical displacement of the mediastinum and stretching of the opposite lung causes a separation of the pleura, rupture of pleural lesions and the subsequent development of fluid.

5. The study emphasizes the need for great caution in dealing with the long-contracted lung.

6. The lung should be allowed to expand slowly under the control of reduced artificial pneumothorax, and with its failure to expand a thoracoplastic operation should be performed in order to bring the pleural surfaces into apposition.

CLINICAL STUDIES OF PRIMARY CARCINOMA OF THE LUNG

AN ANALYSIS OF SEVENTY-FIVE CASES, TWENTY-
ONE OF WHICH WERE TREATED BY PNEU-
MONECTOMY OR LOBECTOMY

RICHARD H. OVERHOLT, M.D.

AND

WILLIAM RAY RUMEL, M.D.

BOSTON

Before a disease entity can be satisfactorily brought under control, the medical profession as a whole must become interested in the disease. In order to arouse interest in the condition, it must be shown that the occurrence is frequent enough to be of practical importance and that something can be offered in the way of efficient therapy. It is our purpose in this paper to show that primary carcinoma of the lung is a disease that deserves this interest. Consideration will be given to its incidence, its early clinical manifestations, the available methods of diagnosis and treatment, and the results of a clinical analysis of seventy-five cases, in twenty-one of which treatment was either by lobectomy or by pneumonectomy.

INCIDENCE

The lung can now be shown to be a common, rather than a rare, site for the development of a primary malignant growth. Autopsy material from general hospitals, where admissions are unselected, is the most reliable source of data on the relative frequency of fatal diseases. A study of 52,305 recently collected autopsy reports (table 1) reveals that approximately 10 per cent of all primary cancers originate in the lungs. The incidence in the various groups ranged between 6.3 and 18.5 per cent. It is startling to learn that in the group of 7,685 consecutive autopsies done in the Cleveland City Hospital and reported by Koletsky,¹ the lung was the second most frequent site of origin of primary malignancy, being exceeded only by the stomach. Also

in the series of 6,800 autopsies reported from the Cook County Hospital, Chicago, by Jaffé,² the lung was in third place, the stomach being first, and the intestine second.

Graham³ has tabulated autopsy reports from various European and American hospitals which have appeared during the past twenty-five years. In all but one report the increase in the frequency of cancer of the lung was striking. In a total of 62,802 necropsies the percentages of primary lung cancers to all cancers were reported (table 2). Simons⁴ has clearly shown that the high incidence of lung cancer today is due both to a relative and to an absolute increase in frequency.

The numerical importance of the problem becomes apparent when it is appreciated that approximately 15,000 people in the United States die each year from cancer originating within the lung. This estimate is based on the statistical study by Dublin,⁵ who finds that approximately 150,000 persons die from cancer of all types each year. Since 10 per cent of all cancer deaths are due to primary carcinoma of the lung, it is fair to estimate the toll from this disease at 15,000 a year.

FAILURE OF IRRADIATION

The only weapons available today in the fight against cancer are radium, x-rays, fulguration and surgical excision. All forms of irradiation have up to the present time failed completely as curative agents. Graham and his associates³ have been unable to find record of a single verified case of a five year cure by this method of treatment. Furthermore, they conclude that high voltage roentgen therapy does not prolong the lives of patients with carcinoma of the lung, because the great majority of the tumors are radioresistent. Our own experience with irradiation has also been disappointing. We have not obtained a single cure by means of this treatment. Also a study of life expectancy of inoperable patients revealed that, on the average, the patients who received high voltage roentgen therapy lived only two thirds as long as untreated patients. The average duration of life in the two groups is shown in table 3.

The failure of irradiation is not surprising, since the majority of lung cancers are situated in the stem bronchi, which places them anatomically as near the center of the body as it is possible for them to be. Thus deliverance of a dosage sufficient to destroy the tumor without irreparable damage to the surrounding tissues is practically impossible. Also pulmonary infection frequently follows bronchial occlusion by the primary growth. In such instances irradiation will often aggravate the inflammatory processes and actually shorten life rather than prolong it. At the present time we believe that the results do not justify the use of high voltage roentgen therapy in any operable case. The same holds true in any inoperable one complicated by pulmonary suppuration, except possibly in an attempt to relieve pain. Irradiation is being given further trial in those inoperable cases presenting no evidence of associated infection.

The intrabronchial insertion of radium for lesions in a stem bronchus and thoracotomy with direct insertion of radon seeds into peripherally located tumors has been

recommended by Edwards.⁶ Beneficial effects were reported in the way of canalization of the bronchus, local disappearance of the tumor, as seen bronchoscopically, and symptomatic improvement. Specific case reports with histologic data were not given. It was admitted, however, that end results as regards cure were necessarily poor.

* Not included in total of 52,305 because it is included in the cases reported by Simons.

We have not considered the evidence supporting the use of radium in treating cancer of the lung convincing enough to justify its use. On theoretical grounds the danger of increasing bronchial obstruction and aggravating the associated suppurative processes far outweighs the remote chance that the tumor would be destroyed or even retarded in its growth. None of the patients in our series have been treated in this way. Treatment of primary carcinomas of the lung by endobronchial fulguration has been reported. Some of the so-called cures by this method have been in cases in which the identity of the tumor was mistaken. It is theoretically possible for a primary cancer, occurring as a small papillary intrabronchial tumor, to be completely removed by this method. Such cases from a practical standpoint, however, are extremely rare. In our experience we have seen but one instance in which the tumor was apparently completely removed bronchoscopically with no evidence of recurrence during a two year period. In every case in our series in which surgical excision was carried out the tumor was found

to have extended through the bronchial wall into the parenchyma of the lung. Obviously, endobronchial therapy would not have been suitable in any of these cases.

DEFINITE HOPE OFFERED BY SURGERY

Fortunately the outlook for the patient with primary carcinoma of the lung now appears to be much brighter, owing to the introduction of surgical excision of lung tissue as a practical therapeutic procedure. The place that this form of treatment will ultimately take in the therapy of primary carcinoma of the lung is yet unsettled. This place will be dependent on three fac-

tors: (1) early diagnosis at a time when excision can be carried out before extension or metastasis has occurred, (2) a relatively low operative mortality rate, and (3) a reasonable chance of cure without excessive permanent disability. With regard to the first prerequisite, it is obvious that almost all the responsibility of early diagnosis falls on the shoulders of the general practitioner, who must suspect obscure pulmonary lesions of being due to primary malignant disease and immediately carry out all the diagnostic procedures that are available to him and then, without delay, ask for whatever aid he may need in carrying out the special examinations that are necessary to prove or disprove the presence of this disease. That a great deal of progress has been made, through the alertness of the physician and his cooperation with the roentgenologist and bronchoscopist, is evidenced by the great difference in percentage of correct antemortem diagnoses made in the past five years, as compared with those made at the beginning of the twentieth century. Sehrt⁷ in 1904 reviewed 178 collected cases, proved by autopsy, and found that the correct antemortem diagnosis was made in only 3.3 per cent of the entire group. In a series of cases of obscure chest lesions studied by us in which the symptoms or examinations suggested primary malignancy, this diagnosis was established histologically

* High voltage roentgen therapy was begun as soon as the diagnosis was established in the cases in which it was used.

in the living subject in approximately 90 per cent. Of the proved cases, 24 per cent were diagnosed at an operable stage and pneumonectomy or lobectomy was carried out. With continued interest in the problem there is no reason why the percentage of clinical discoveries at an operable stage should not steadily increase. It can be shown that progress has been made with regard to the surgeon's ability to resect a human lung safely. Between 1933 and 1936 one of us (Overholt) resected an entire lung for a primary malignant growth or for pulmonary suppuration in twelve cases, with an operative mortality of 33 1/3 per cent. Between 1937 and 1939 the operative mortality rate in twelve cases similarly treated was 16 2/3 per cent. These figures compare favorably with those pertaining to total resection of abdominal organs for malignant conditions and are certainly not prohibitive when it is realized that a disease is being dealt with that is 100 per cent fatal without surgical treatment. With regard to the third prerequisite, our present knowledge of the ultimate outcome of the patient who has been subjected to pneumonectomy should certainly make us feel hopeful. The first patient treated by Overholt survived pneumonectomy for primary cancer of the lung and is still living and well with no evidence of recurrence five years and four months after operation. The second patient will pass the five year mark in one month, and others have been living without evidence of recurrence for shorter postoperative periods. These

7. Sehrt, quoted by Simons.⁴

patients carry on normal lives, are not unduly limited in their physical activities and show no obvious deformity.

CLINICAL AND PATHOLOGIC CONSIDERATIONS

The great variation of symptoms and clinical manifestations found in primary carcinoma of the lung can be better understood by first considering the pathologic changes that produce them. The general consensus now is that all primary carcinomas of the lung arise from a single undifferentiated parent cell located in the basal layer of the bronchial epithelium, regardless of whether the site of origin is in the main stem bronchi or in the terminal bronchioles.⁴ The degree of differentiation of this parent cell determines whether the tumor will be a squamous cell carcinoma, an adenocarcinoma, an undifferentiated round cell, spindle cell or "oat cell" type, or a combination of two or more of these, which is seen not infrequently. From a clinicopathologic standpoint the symptoms and signs may conveniently be divided into several stages. This division will obviously not be

possible in every case but will probably prove helpful in most instances.

1. Stage Before Bronchial Occlusion.—Soon after the tumor begins to grow, its presence causes irritation of the sensitive bronchial mucosa, which results in a dry, irritative cough. This is by far the earliest, most constant and therefore most important symptom in the majority of cases. Since the cough is ineffectual in removing the irritating agent, an increased amount of bronchial secretion is produced in an attempt to wash out the irritant. This results in the next frequent early

2. Stage of Bronchial Occlusion.—A. Partial Occlusion with Emphysema: Further increase in the size of the tumor causes partial obstruction of the bronchus. In spite of this, air can still be forcibly drawn past the obstructing tumor during the powerful inspiratory phase of respiration. It is impossible for this air to escape completely from the affected segment of lung because

Fig. 2.—Effects of bronchial occlusion due to early carcinoma: A, lung segment normal before occlusion; B, segmental emphysema due to partial occlusion; C, segmental atelectasis due to complete occlusion.

the relatively weak elastic recoil of the lung tissue is not strong enough to force all the inspired air past the point of obstruction before the next inspiration occurs. This results in emphysema of the segment of lung supplied by the affected bronchus and produces the wheezing or asthmatic breathing which is another frequent early symptom. On physical examination during this stage of the disease a hyperresonant percussion note may be found over the involved area. The breath sounds are often emphysematous, with moist expiratory rales and rhonchi. The roentgenogram may show a wedge-shaped area of decreased density with convex limiting borders (fig. 2). Partial occlusion of a bronchus is responsible for the erroneous diagnosis of asthma which is not infrequently made. In the great majority of cases this phase of the disease is apt to be of short duration, owing to the relatively small size of the bronchial lumen and the rapidity with which even a small growth will produce complete occlusion.

Fig. 1.—Chest of Mr. I. B. Note that the slight alteration in the axis of the ribs, the slight shift of the heart to the right and the minimal amount of increased density adjacent to the right heart border could very easily be overlooked. Because of the persistent cough and discomfort in the chest, even in the absence of definite roentgenologic changes suggesting carcinoma of the lung, a bronchoscopic examination was done. A small tumor in the stem bronchus of the right lower lobe was seen and a biopsy specimen obtained bronchoscopically. Microscopic examination proved it to be a primary epidermoid carcinoma grade 2. Pneumonectomy was successfully carried out.

symptom, which is a clear, thin, mucoid sputum. As the tumor enlarges, the trauma from coughing, as well as the tendency for the tumor tissue to undergo degeneration, produces ulceration of its surface, which accounts for the appearance of blood streaked sputum and a tendency for the sputum to become purulent. These are both frequent early symptoms. Physical manifestations and changes demonstrable on the roentgenogram are not present during this stage, because the tumor is not large enough to cast a shadow and the changes incident to bronchial occlusion have not yet appeared. Still it is important to realize that the diagnosis usually can be definitely established by bronchoscopic examination, even at this early period, because the majority of primary carcinomas of the lung arise in the stem bronchi, so that they fall within the range of bronchoscopic accessibility (fig. 1).

Fig. 3.—Chest of Mrs. E. H., showing a diffuse homogeneous shadow in the postero-anterior exposure produced by atelectasis of the lingular segment of the left upper lobe. The lateral exposure localizes the atelectatic segment to the anterior-inferior portion of the upper lobe. Note the absence of marked mediastinal shift, elevation of the diaphragm and narrowing of the intercostal spaces due to the ability of the lower lobe and uninvolved portions of the upper lobe to compensate for the shrinkage of the lingular segment. Bronchoscopic biopsy proved the tumor to be a carcinoma simplex. This patient is well, with no evidence of recurrence, four years eleven months after pneumonectomy.

B. Complete Occlusion with Atelectasis: The complete occlusion of the bronchus to a segment of lung or a lobe produces still a different picture. Atelectasis occurs and the airless segment becomes shrunken and functionless. Dyspnea, which is another frequent early

symptom, appears not alone because of the decrease in lung volume but also probably because of the mediastinal shift, which displaces the trachea and interferes with heart action. The discomfort or feeling of weight and constriction in the chest so often noted during this period is probably due to a reflex spasm of the intercostal muscles and the smooth muscle in the walls of the bronchial tree. Pain of any severity is not a part of the picture of early carcinoma of the lung and, when present, is usually due to pleurisy resulting from a complicating inflammatory process. The absence of pain should not be considered evidence against the presence of primary carcinoma of the lung. The severe pain usually described as being an outstanding symptom of this disease occurs in the later stages as a result of extension or metastasis of the tumor to the pleura, bones, nerve structures or other organs.

Atelectasis is by far the most frequent pathologic change giving rise to physical manifestations at an early stage. The manifestations incident to uncomplicated atelectasis are diminished to absent tactile fremitus, dullness to flatness on percussion and diminished breath sounds, which, if audible at all, are of bronchovesicular or bronchial quality. Associated with these changes will be a varying degree of mediastinal shift toward the affected side, with diaphragmatic elevation and narrowing of the intercostal spaces. The roentgenologic

Fig. 4.—Effects of bronchial occlusion plus infection: A, segmental atelectasis with diffuse pneumonitis; B, segmental atelectasis with large abscess showing fluid level; C, segmental atelectasis with pneumonitis and multiple cavities.

appearance is again due, in most cases, to atelectasis, which characteristically produces a dense, wedge-shaped shadow with concave borders extending from the hilus out to the chest wall (fig. 2). It must be remembered that, if the atelectatic segment extends from the hilus posteriorly or anteriorly, the shadow may not appear to reach the periphery of the lung in the anteroposterior film; but if lateral and oblique exposures are taken it may clearly be shown to do so (fig. 3). These additional films are important in a study of patients suspected of having bronchial occlusion. An excellent treatise on the roentgenologic aspects of bronchostenosis, which is well worth studying, has recently been prepared by Westermarck.⁸ Again, a varying degree of mediastinal shift, diaphragmatic elevation and narrowing of intercostal spaces will be associated, depending on the size of the segment of the atelectatic lung. It is notable that the tumor per se casts a shadow on the roentgenogram in only a small percentage of cases at an early stage. This is more apt to occur in peripherally located lesions.

C. Bronchial Occlusion with Secondary Infection: With bronchial occlusion and ulceration, secondary infection of the bronchial tree usually occurs because the ability of the ciliated epithelial cells to sweep out contaminating bacteria is impaired. This may progress into bronchitis, bronchiectasis, varying degrees of pneu-

monitis, abscess or even gangrene of an entire lung. The type of infection that develops depends mainly on the size of the affected bronchus and the virulence and type of infecting organisms present. In the cases of carcinoma collected by Simons,⁴ approximately one third of the entire group presented evidence of pulmonary infection. One must therefore be aware of the frequent occurrence of secondary infection and not be found guilty of treating a patient for "unresolved pneumonia," "bronchitis" or "pleurisy" while he is dying of primary carcinoma.

The symptoms and signs that appear during this phase of the disease obviously will vary considerably, depending on the nature and severity of the complicating inflammatory lesions and the prominence of the symptoms and signs due to the uncomplicated bronchial occlusion. With the development of diffuse bronchitis or bronchiectasis, cough productive of a varying amount of more or less purulent sputum will be present. If the tumor now causes complete obstruction to drainage from the bronchial tree the patient will soon become acutely ill, owing to the pulmonary infection, and may present the clinical picture of pneumonia. Drainage may suddenly be reestablished owing to breakdown of the obstructing tumor or decrease in the surrounding edema, so that the patient may expectorate a large amount of sputum, after which he will feel much better until the bronchus again becomes occluded. The acute pneumonic symptoms will then reappear. Such a sequence of events is relatively common and is responsible for the diagnosis of "recurrent pneumonia" which is made at times. If there is considerable destruction of the lung due to infection or breakdown of the tumor, cavitation will result. Thus lung abscess may be closely simulated, since in reality abscess in this phase of the disease would be the outstanding pathologic process present (fig. 4). With the development of other inflammatory lesions, other symptom complexes will be found.

As might be expected, the observations made on physical examination during this phase of the disease are also extremely variable and are not characteristic of carcinoma of the lung, since there are so many factors involved in their production. If the suppurative complications predominate, the usual signs of bronchitis or bronchiectasis or of the consolidation resulting from pneumonitis will be present. If cavitation occurs following excavation of an abscess, changes due to this lesion will be present. Now when one sees a case in which manifestations resulting from the inflammatory lesions are intermingled with those resulting from the primary partial or complete bronchial occlusion it becomes apparent that there may be an endless number of different physical conditions found.

The roentgenologic appearances present during this stage are those of the uncomplicated bronchial occlusion already described plus the changes incident to the various inflammatory processes that may be present. The homogeneous appearance of the atelectatic shadow is frequently mottled by the infectious process, and at times multiple small areas of cavitation appear. Also the margins of this shadow are often hazy and indefinite, owing to adjacent pneumonitis (figs. 4 and 5).

3. Stage of Extension or Metastases.—There are many other symptoms, physical signs and roentgenologic changes that are due to extension of the tumor or metastases, such as dysphagia, abnormal symptoms of the central nervous system, phrenic nerve paralysis, dilated veins of the neck, chest wall or upper extrem-

8. Westermarck, Nils: On Bronchostenosis: A Roentgenological Study, *Acta radiol.* 19: 285, 1938.

ities, and diffuse carcinomatous infiltration of the lung; but these are all signs of the disease at a time when the possibility of cure has passed and are therefore relatively unimportant clinically, so they will not be considered further.

In considering the effects of bronchial occlusion in the various stages mentioned, it is important to realize that the severity of symptoms and the prominence of physical and roentgenologic changes will be directly proportional to the size of the affected bronchus. Thus, if a main stem bronchus is occluded, the symptoms will be severe and the appearances unquestionable. However, if a small peripheral bronchus is affected the symptoms will be insignificant, the physical manifestations will be localized to a small area so that they will almost surely be overlooked, and the roentgenologic changes will be minimal. It is important also to be aware of the fact that the shadow cast on the roentgenogram incident to bronchial occlusion may not correspond exactly to the gross anatomic distribution of one of the five pulmonary lobes because, in the first place, only one branch of one of the lobar bronchi may be affected, and, in the second place, the shadow will be distorted, in the case of emphysema by distention and enlargement and in the case of atelectasis by collapse and shrinkage.

It should be emphasized that symptoms and signs of one or all of the aforementioned stages may be present at one time. This is possible because, for example, a tumor arising in the main middle lobe bronchus may produce complete obstruction, with atelectasis of the entire middle lobe, while the extrabronchial portion of the same tumor may produce partial occlusion of the bronchus of the lower lobe resulting in emphysema of the lower lobe. Thus two stages may be represented at one time. Now, if infection develops in either the atelectatic or the emphysematous segment, symptoms and signs of a third stage may appear. If the tumor metastasizes, manifestations of the terminal stage may also be present.

ANALYSIS OF AUTHORS' SERIES OF CASES

This analysis is based on the study of seventy-five cases in which the diagnosis of primary carcinoma of the lung has been proved histologically. The only significant predisposing etiologic factors found were age and sex. The average age of these patients was 50 years; the youngest was 18, and the oldest 68. Fifty-four of the patients were men and only twenty-one were women, a ratio of 2.6 to 1.

For the purpose of study these patients were arbitrarily separated into two groups, one in which the tumors were located in a stem bronchus and the other in which the lesions were located peripherally. In the stem bronchus group there were fifty-seven cases (76 per cent) and in the peripheral group eighteen cases (24 per cent). The main practical difference between the two groups is that the lesions in the stem bronchus group fall within the range of the bronchoscope, which facilitates preoperative diagnosis, while the tumors located peripherally are not accessible to bronchoscopic examination. Therefore, in most of these cases exploratory thoracotomy must be done to establish the diagnosis definitely. Some of these tumors may possibly be removed by lobectomy rather than by pneumonectomy, owing to their distant location from the hilus.

SYMPTOMS

The symptoms found in this series of cases and the relative frequency of occurrence in the two groups is

shown in table 4.⁹ Cough was by far the most common and earliest symptom, being present in 87 per cent of the entire group. At the onset in most cases it was dry and irritative. It soon became productive of a clear, odorless, mucoid sputum which, as the disease progressed, changed to a more purulent character, depending on the amount of infection and ulceration that developed. Fever was present in 53 per cent of the cases and was definitely more frequent in the stem bronchus group. This again brings up the importance of recognizing the frequent occurrence of secondary inflammatory changes, which often dominate the clinical picture and mask the presence of the primary lesion until the operable stage of the disease has passed. Chest pain or discomfort, in the form of a dull ache or heavy sense of constriction, was present in 44 per cent. Pain of any great severity was not found early in the great majority of cases and, when present, could be accounted for by inflammatory processes. Hemoptysis was present in 38 per cent of the total group and was more common in the peripheral lesions. This was, at an early stage, streaking of the sputum with bright red blood and, less frequently, raising of old blood of a brownish red color.

TABLE 4.—Occurrence of Symptoms in Authors' Cases

Symptoms	Stem Bronchus Group (52 Cases)		Peripheral Group (16 Cases)		Entire Group (68 Cases)	
	Num- ber	Per Cent	Num- ber	Per Cent	Num- ber	Per Cent
Cough.....	46	88.4	13	81.2	59	86.7
Fever.....	29	61.5	7	43.7	36	52.0
Pain or discomfort.....	21	40.3	9	56.2	30	44.1

Weight loss.....	18	34.6	8	50.0	26	38.2
Dyspnea.....	16	30.7	5	31.2	21	30.8
Weakness.....	10	19.2	1	6.2	11	16.1
Chills.....	8	15.3	0	0.0	8	11.7
	5	9.6	1	6.2	6	8.8
	5	9.6	0	0.0	5	7.3

Note: Sputum not represented but was present in majority of cases in which there was cough.

Massive hemorrhage occurred only in advanced cases. Dyspnea or wheezing was present in 38 per cent of the cases and was frequently an early symptom. The other symptoms mentioned in table 4 were present in the more advanced cases. No group or complex of symptoms was found which could be called characteristic of the disease.

PHYSICAL SIGNS

Physical manifestations were present in 93 per cent of all cases but were so variable that little reliance was placed on them. They usually simulated the pathologic changes produced by the conditions from which carcinoma of the lung must be differentiated.

ROENTGENOLOGIC ASPECTS

Definite changes were present on the roentgenogram in 96 per cent of the cases. The most frequent finding was the shadow cast by the tissue of the atelectatic lung, in lobar or lobular distribution, with the accompanying changes in the mediastinum and thoracic cage previously mentioned (fig. 3). These changes were present in 85.3 per cent of all cases. In a small number of cases, changes resulting from segmental emphysema were associated. Evidences of a

9. The figures regarding the occurrence of symptoms are taken from a study of sixty-eight cases recently reported (Overholt, R. H., and Rumel, W. R.: Clinical Studies of Primary Carcinoma of the Lung, Journal-Lancet 50: 155 [April] 1939).

superimposed inflammatory process were also frequently present (fig. 5). A shadow of the tumor itself was cast in only 17 per cent of the cases, and the majority of these were in the peripheral group. Here the shadow produced was in the form of a rounded area of increased density with a margin, which in some cases, was quite smooth and well demarcated from the

Fig. 5.—Chest of Mr. J. F., showing the shadow produced by atelectasis of the left upper lobe with additional changes incident to secondary infection. The mottling due to diffuse pneumonitis and multiple abscess formation is best shown on the overexposed film. Bronchoscopy with biopsy proved the primary lesion to be an undifferentiated carcinoma originating in the bronchus of the left upper lobe. The lesion was found to be inoperable at the time of bronchoscopic examination.

surrounding lung tissue (fig. 6), while in others it was softer, infiltrative and more irregular. The dense, homogeneous, wedge-shaped shadow with concave margins typical of atelectasis, often associated with a shift of the mediastinum, was found to be quite characteristic. However, this appearance does not invariably indicate the presence of primary carcinoma of the lung, since any lesion which obstructs a bronchus can produce such a shadow.

DIAGNOSTIC PROCEDURES

I. Bronchoscopy.—Bronchoscopic examination is by far the most valuable single diagnostic procedure in studying patients suspected of having primary cancer of the lung, for the following reasons:

1. Approximately three fourths of all primary lung tumors are situated in the major bronchi, so that they are within the range of bronchoscopic vision. In our group of fifty-five stem bronchus lesions in which bronchoscopy was done a biopsy of tumor tissue was obtained in fifty-three instances, thus furnishing microscopic proof of the diagnosis.

2. Bronchoscopy is the only safe and practical means of obtaining a biopsy in the stem bronchus group. This cannot be said for transthoracic aspirational biopsy.

3. In the great majority of cases the diagnosis can be made much earlier than by any other method.

We feel, therefore, that there is no real justification for postponing bronchoscopic examination of a patient in whom a dry or productive cough develops, alone or associated with hemoptysis, wheezing, dyspnea, chest discomfort or other symptoms suggestive of early primary carcinoma of the lung that cannot be definitely explained on some other basis. We feel that this is true even in the absence of physical manifestations and roentgenologic changes, especially if the patient is of "cancer age" and has previously been symptom free. We can see no logical reason why one should await the development of additional symptoms, physical signs or abnormalities on the roentgenogram when these

changes, even at an advanced stage of the disease, furnish merely presumptive evidence of the presence of primary carcinoma of the lung.

Aside from being the most important diagnostic procedure available, bronchoscopy is also valuable in determining the operability of a given tumor and at times it is helpful as a therapeutic measure. If a tumor is seen on bronchoscopic examination to extend into the wall of the trachea, it may have to be considered inoperable from a technical standpoint. If the trachea and mediastinal structures are firm and fixed, or if the angle of the carina is widened or distorted, it is very probable that these changes are due to the growth of metastatic tumor tissue in the mediastinal glands around the bifurcation of the trachea, thus making the case inoperable.

A patient may become gravely ill as a result of pulmonary suppuration distal to an obstructing tumor, which prevents adequate drainage of pus from the bronchial tree. In such cases bronchoscopic dilation may temporarily relieve the obstruction and improve the patient's general condition, enabling him to withstand excision of the tumor, which he would otherwise be unable to tolerate. It is important to know that a patient may be seriously ill because of secondary suppurative processes in the lung and still have a cancer that has not become inoperable. Such a patient certainly deserves a bronchoscopic examination, followed by whatever endobronchial or surgical treatment is deemed advisable by the thoracic surgeon.

Since bronchoscopic examination is such an important part of the routine study of the patient presenting symptoms or signs which may be due to primary carcinoma of the lung, it is hoped that this procedure will not be used as a last resort in making a diagnosis after all other methods have failed and much valuable time has been wasted. The importance of delay can be better

Fig. 6.—Chest of Mr. R. B., showing a round, well circumscribed peripheral shadow in the right lower lobe cast by a bronchiogenic adenocarcinoma. No evidence of extension of the tumor was found at the time of exploratory thoracotomy, so lobectomy was performed. The patient survived the operation and is at present perfectly well, with no evidence of recurrence, sixteen months after the operation.

understood if it is realized that a disease is being dealt with in which the time from appearance of symptoms until death is short, as is shown in the following groups of cases: Jaffé² approximately five months, Frissell and Knox¹⁰ approximately seven and one half months and Koletsky¹ approximately nine months. It becomes obvious that if one expects to save the patient who is suffering from a disease which runs such a rapid course one must act quickly in arriving at the cor-

rect diagnosis before the stage of operability has passed. The following thought expressed by Rienhoff,¹¹ seems especially applicable to the subject under consideration.

10. Frissell, L. F., and Knox, Leila Charlton: Primary Carcinoma of the Lung, *Am. J. Cancer* 30: 219 (June) 1937.

11. Rienhoff, W. F., Jr.: Carcinoma of the Lung, *Surgery* 1: 125 (Jan.) 1937.

He says: "Our clinical pace must be quickened, for until recently the great majority of recognized affections of the respiratory tract have been those in which Time was felt to be the Great Healer, but with the development of methods by which patients can not only be relieved but cured of malignant neoplasms of the lung, it may be said that Time now takes on the role of executioner."

Fig. 7.—Artist's reproduction of the left lung of Mr. J. S., which was surgically removed. To facilitate illustration, the specimen was sectioned through the stem bronchi to expose the tumor. From its point of origin in the bronchus of the left upper lobe the tumor had extended peripherally through the parenchyma of the lung to produce a sunken, puckered appearance of the opposite visceral pleura (inset). Microscopic examination proved the tumor to be an epidermoid carcinoma grade 3. Unfortunately this patient died after the operation.

II. Bronchography after the injection of iodized oil may aid in the diagnosis of tumors which are out of the range of bronchoscopic vision, but we feel that this procedure should be used only if the results of bronchoscopy are negative. Reliance cannot be placed on a negative bronchographic examination alone, and if it is positive bronchoscopy must still be carried out to complete the study of the case by visualizing the tumor and obtaining a biopsy specimen for microscopic examination.

III. The demonstration of malignant tissue in the sputum, as reported by Dudgeon and Wrigley¹² and later by Barrett,¹³ has in a limited series of our cases proved disappointing.

IV. Aspirational biopsy is a dangerous procedure, since pleural infection may follow withdrawal of a needle from an infected lung through the pleural space, and we feel that it has no clinical value except to establish the diagnosis in cases which are obviously

inoperable. This statement is believed to be true because, if the biopsy is positive in a suspected case without clinical evidence of metastasis, exploratory thoracotomy is indicated, and if the biopsy is negative in the same type of case the same exploration is still the next step in its management.

V. Exploratory thoracotomy was carried out in thirty-eight (50.6 per cent) of the seventy-five cases in this series. None of these patients had demonstrable evidence of metastasis before exploration. We believe that this procedure is indicated in any case in which the diagnosis of primary carcinoma of the lung has been established or is suspected, because of the presence of suggestive symptoms, physical manifestations or roentgenologic changes, just as an exploratory laparotomy is indicated in a suggestive lesion in the stomach or bowel, where the presence of a malignant growth cannot be excluded. Fortunately in the majority of instances the diagnosis can be proved preoperatively by bronchoscopic examination. In most cases in which this is not possible the tumors are located peripherally, so that the diagnosis can be definitely established at the time of exploration. Before thoracotomy is done, one should be sure that there is no clinical evidence of metastasis. Careful neurologic examination should be done to rule out involvement of the central nervous system. Biopsy of enlarged cervical glands should be done if they are found. Skeletal roentgenograms should be taken to rule out metastases to the bones. Fluoroscopic examination should be carried out to exclude the presence of diaphragmatic paralysis, since this is almost a sure sign of extension of the disease. Mediastinal infiltration should be ruled out by bronchoscopic examination.

OPERABILITY

In the group of seventy-five cases lung resection was carried out in twenty-one—pneumonectomy in seventeen and lobectomy in four (fig. 7). Fulguration was possible in only one instance. Two cases in which

Fig. 8.—Mrs. T. K. as she appeared two years and four months after pneumonectomy for a primary small cell carcinoma of the left upper lobe. She feels perfectly well and has done all her work as a housewife for the past two years. Note the absence of significant deformity and the satisfactory state of nutrition of this patient.

resection was done were apparently operable at the beginning of the operation, but before the excision was completed evidence of mediastinal metastasis was found. In two other cases extension of the tumor into the chest wall had occurred. These were treated by removal of a block of chest wall with the affected lung. In the final analysis there were eighteen cases (24 per

12. Dudgeon, L. S., and Wrigley, C. H.: On the Demonstration of Particles of Malignant Growth in the Sputum by Means of the Wet-Film Method, *J. Laryng. & Otol.* 50: 752 (Oct.) 1935.

13. Barrett, N. R.: Examination of the Sputum for Malignant Cells and Particles of Malignant Tissue, *J. Thoracic Surg.* 8: 169 (Dec.) 1938.

cent of the entire group) in which no evidence of metastasis or extension of the tumor was found at the time of the operation.

RESULTS OF SURGICAL TREATMENT

Of the four patients treated by lobectomy, three recovered from the operation and were discharged as improved. One patient had direct extension of the tumor into the chest wall and another had metastases to the mediastinal glands which were resected. Both of these patients have since died. The third patient died after the operation, and the fourth is living and well sixteen months after the operation.

In the group of seventeen for whom pneumonectomy was done, six patients died within two months of the operation; these deaths are considered operative deaths. Three patients died after making an operative recovery. It is significant to note that only one of these succumbed as a result of definite recurrence of malignant disease. This death occurred six months after the operation. The second patient died a year after the operation as a result of a psychosis. Complete postmortem examination of this patient revealed no evidence of a malignant growth. The third late death occurred two years after operation, from an unknown cause. Unfortunately an autopsy permit was not obtained. However, three and one half months before death the patient had no demonstrable evidence of a recurrent malignant growth on clinical and roentgenologic examination.

Eight patients treated for primary lung cancer by pneumonectomy are living and well with no evidence of recurrence of the malignant condition. They are all able to carry on the same activities in which they were engaged before the operation. Not one has significant cardiorespiratory embarrassment and, when clothed, not one has obvious deformity (fig. 8). The longest periods of survival postoperatively are five years four months, four years eleven and one-half months and two years ten and one-half months.¹⁴

CONCLUSIONS

1. Primary carcinoma of the lung is a relatively common disease which is responsible for approximately 10 per cent of all cancer deaths.

2. In this clinical study seventy-five patients had histologically proved primary carcinoma of the lung.

3. Partial or complete bronchial occlusion, with or without secondary infection, produces the most important pathologic lesions giving rise to early symptoms, physical manifestations and roentgenologic changes.

4. Bronchoscopic examination is by far the most important diagnostic procedure available and should be used without delay in the study of any case in which a dry or productive cough develops alone or in association with hemoptysis, wheezing, dyspnea, chest discomfort or other symptoms suggestive of early primary carcinoma of the lung that cannot be definitely explained on some other basis.

5. The diagnosis was established with histologic verification at an operable stage in 24 per cent of the seventy-five cases.

6. Lobectomy and pneumonectomy are practical therapeutic procedures, without an excessive operative mortality rate, which at the present time appear to offer a good chance of survival to the patient suffering from primary carcinoma of the lung.

1101 Beacon Street, Brookline.

14. At the time the authors' proof was submitted, Feb. 3, 1940, all of the patients were still alive and well without evidence of metastatic disease. The longest survival periods were then six years three months, five years ten months and three years ten months.

PREVENTIVE PEDIATRICS

WILBURT C. DAVISON, M.D.

DURHAM, N. C.

Whether or not the cost is borne by taxation, private fees or local charity,¹ prevention is the most important phase of pediatrics and should be extended both by general practitioners and by pediatricians. "He who cures a disease may be the most skilful, but he who prevents it is the safest physician." Three fourths of the quarter of a million annual deaths of American children² can and should be prevented. Twenty-one per cent of these deaths are due to curable diseases, while 56 per cent are caused by preventable conditions (table 1). The public should be educated to utilize the facilities available at present.¹

During the last thirty-three years much has been accomplished, and the infant mortality rate in New York City, for example, has fallen from 140 per thousand living births to 55. This decrease has been mainly in the diarrheal deaths and probably is due to a better milk supply and more intelligent infant feeding. The mortality rate of tuberculosis and the respiratory and infectious diseases also has been reduced, though to a lesser extent. Unfortunately, the diseases peculiar to early infancy kill nearly as many now as in 1898. In spite of a general belief to the contrary and although still more must be done, the reduction in infant mortality in the United States can be compared favorably with that of many other civilized countries. For instance, in 1900, 190 of every thousand German infants and 290 per thousand of those in Breslau died during their first year, while in 1933 only 80 per thousand succumbed.³ In this country, in 1915 the infant mortality under the age of 1 year was 100, but in 1936 it was 57.⁴ During this period, the reduction in the deaths among infants in the second to the twelfth month of life was 56 per cent but in those in the first month of life only 27 per cent. The variation in infant mortality, however, in the several states leaves much to be desired, ranging from a maximum of 136 in one state to a low point of 39 in the state of Washington.

ANTEPARTUM, INTRAPARTUM AND POSTPARTUM CARE

The problem of prevention can be simplified by dividing it into its two constituent parts, antepartum (including intrapartum and neonatal measures) and postpartum care. The need for better antepartum, intrapartum and neonatal care is emphasized by the fact that over half of the deaths in this country under the age of 1 year (thirty-four of fifty-seven) occur under the age of 1 month (table 2).⁴ Improved antepartum care and the antepartum hospitalization of mothers who need it can and must be supplied through the cooperation of general practitioners, obstetricians, pediatricians, health officials, nurses and hospitals. That such joint effort is efficacious has been demonstrated

From the Department of Pediatrics, Duke University School of Medicine, and Duke Hospital, with the cooperation of Drs. J. A. Hayne, W. F. Draper, J. M. Eberhart, Oren Moore, Hayard Carter, L. T. Royster and William Weston (Report of a Committee on Infant Mortality in North and South Carolina, and Virginia) and of Miss Judith Farrar, Librarian of Duke Hospital.

4. Summary of Live Birth, Infant Mortality and Stillbirth Statistics in the United States, 1933, Department of Commerce, Bureau of the Census; United States Department of Labor, Children's Bureau, Sept. 14, 1935 (3036). Personal communication from Dr. Martha M. Elliot and Dr. T. F. Murphy.

by Gengenbach and his associates in Denver, who reduced the number of infant deaths from 178 per thousand live births to 15 per thousand by antepartum measures.⁵ If further proof is required of the need for more and better antepartum care it is supplied by the increase in infant deaths in Durham County, N. C., from 1932 to 1935.⁶ As this increase was only among white infants under 1 month of age, it seems logical to assume that many of the white mothers who prior to 1930 could afford antepartum care are not seeking it now, as a result of the depression. Charity antepartum and obstetric clinics are available, but many mothers still regard antepartum care as an unessential luxury. Should not greater efforts be made to persuade expectant mothers not only of the advisability but of the necessity of visiting their physicians or these antepartum clinics at frequent intervals? The antepartum, intrapartum and neonatal measures necessary for the reduction of infant mortality are simple and within the reach of many expectant mothers and of every competent physician.⁷ Ignorance of the necessity for antepartum care probably is as important a factor in infant mortality as are poverty and the lack of facilities. One of the main difficulties is in establishing contact between the mother and the physician. The child health program sponsored by the United States Children's Bureau, state and county boards of health and the American Academy of Pediatrics¹ emphasizes this aspect of the problem, through publicity methods urging expectant mothers to go frequently to their physicians as well as through the establishment of antepartum clinics at which obstetric and also contraceptive advice can be obtained.

In order to insure the greatest health to an infant, the prevention of disease should commence as soon as the mother knows that she is pregnant, as her health as well as that of her unborn infant is greatly affected during this period. The changes in organs are sudden. There is a double load on the heart and kidneys. Metabolism is speeded up, and the importance of diet and its effect on both mother and child cannot be overemphasized. Children would be born with a much

die during gestation or in early infancy. These deaths can be prevented by the adequate insulin therapy of the mother, especially during delivery, and by the intramuscular injection of 10 cc. of 5 per cent dextrose in saline solution into infants to prevent the hypoglycemia which usually occurs during the first few hours of life.¹⁰ The infants of diabetic mothers are larger than the average, and the pregnancy sometimes should be interrupted after the eighth month or whenever the fetus weighs more than 3 Kg. (6½ pounds). No patient requires more frequent and detailed checking than does the expectant mother.

Prematurity.—Sixty per cent of infant deaths occur in the first month of life, and nearly half of them are

TABLE 2.—Causes of Pediatric Deaths* Which Can Be Reduced by Better Antepartum, Intrapartum and Neonatal Care

due to prematurity. Seventy per cent of the deaths of these premature babies take place in the first twenty-four hours; this is more than double the percentage of deaths of full term infants during the first day. The improper use of drugs, analgesics and anesthesia, toxemia of pregnancy, pneumonia and syphilis are responsible for many of the premature deaths. The administration of morphine to the mother within four hours before delivery greatly increases the mortality among premature infants. The most common causes of death associated with prematurity are chilling, injury during resuscitation, malformation and pneumonia. The longer the delivery of a premature infant can be delayed, the greater is the weight of the fetus and the lower the infant mortality, although if the mother has toxemia the risk of a stillborn infant is increased.

Birth Injury.—This factor is the next most common cause of death during the first ten days of life. To reduce its frequency, every pregnant woman should have the diagonal conjugate diameter of her pelvis (from the under surface of the symphysis pubis to the promontory of the sacrum, normally 11.5 to 12.5 cm., or 4½ to 5 inches) measured with a sterile gloved hand in the vagina; if the distance is less than 9.5 cm. (4 inches) she should be delivered in a hospital. Other pelvic measurements are useful, but that of the diagonal conjugate diameter is essential. Most of the maternal and infant deaths due to delivery would be prevented if all births were supervised with sterile surgical technic (not hurried) by competent family physicians, by obstetricians or by trained nurses who have had special obstetric training (not that of the usual midwife). The use of oxytocic preparations and of interfering procedures to initiate labor or to speed delivery greatly increases infant and maternal mortality. A bulletin⁷ on this subject can be obtained from the United States Children's Bureau, Washington, D. C.

Stillbirths and Other Deaths of Early Infancy.—Mortality can be reduced if every pregnant woman has her blood pressure determined and her urine, heart and

Remainder.....	207	23

* Percentage of total pediatric mortality in the United States.

better nutritional foundation if those who look after pregnant women would more carefully apply the available information concerning diet during pregnancy rather than, as is so often the case now, merely saying "Just eat a good general diet," if they mention diet at all.⁸ Diet during the last two months of pregnancy is particularly important.⁹ Disease of the mother, such as toxemia, nephritis, diabetes, heart disease, tuberculosis or syphilis, also is an important cause of neonatal mortality. Fifty per cent of the infants of diabetic mothers

lungs examined every month during gestation. If the blood pressure is elevated, if the urine contains albumin or sugar or if the woman has vomiting, convulsions, vaginal bleeding, anemia, infections or any cardiac, thyroid, pulmonary or toxic symptoms, she should obtain competent medical or obstetric advice and treatment. The oftener a pregnant woman visits her physician, the greater is the probability of her having a normal living infant.¹¹ The mother also should visit her dentist two or three times during pregnancy so that her teeth may be kept in good condition.

Atelectasis, Asphyxia and Suffocation.—These conditions often can be eliminated if the mother is not given sedatives during delivery and if the newborn infant, after the air passages are cleared by gentle wiping or suction with a catheter, is given inhalations of 5 per cent carbon dioxide in oxygen for five minutes every four hours for the first day of life. A tracheal catheter may be necessary. Gentle mouth to mouth insufflation is recommended for resuscitation. Patting the soles of the infant's feet before each feeding to insure lusty crying also is useful for atelectasis.

Gonorrheal Ophthalmia.—This disease can be prevented entirely if two drops of a fresh 1 per cent solution of silver nitrate are carefully placed in each eye

of the infant (Credé method) immediately after birth (not on the cheeks or closed eyelids, as occasionally happens). In addition to these initial drops of silver nitrate, the instillation of 20 per cent mild protein silver in each eye once daily for the first three days of life is recommended.¹²

Impetigo Neonatorum.—This disorder is rare if, after the excess blood is wiped off at birth, the skin, except that of the buttocks, is not cleaned again for nine days, i. e. if the vernix caseosa is left intact. The use of various antiseptic oils and the application of 1 per cent copper oleate or 2 per cent ammoniated mercury also are efficacious.¹³

Syphilis of the Newborn.—Syphilis neonatorum can be eliminated if every pregnant woman has a Wassermann, Kahn or Laughlin test as early as possible in pregnancy. If it is negative and the symptoms or the history suggests syphilis, the test should be repeated. If the Wassermann test is positive, it also should be repeated as false positive as well as false negative reactions occur. Antisyphilitic treatment should be started as soon as a diagnosis of syphilis is made by a Wassermann test or the history, preferably before the fourth month of gestation; it should be continued

throughout pregnancy and not stopped until serologic tests are persistently negative. A Wassermann, Kahn or Laughlin test¹⁴ also should be made for every child who is examined for the first time, but treatment should not be started until the serologic evidence is conclusive or spirochetes are found by dark field examination. For every case of syphilis diagnosed clinically, at least five are discovered by routine serologic tests. Roentgenograms of the bones usually are diagnostic by the age of 2 months but should be confirmed by repeated Wassermann tests. Knowing the Wassermann reactions of the patient's parents is helpful but not diagnostic, as 20 per cent of syphilitic women are seronegative and 25 per cent of the children of syphilitic mothers are normal. If the child has syphilis, anti-syphilitic treatment should be continued for at least seventy-five weeks.

POSTPARTUM MEASURES

The medical profession knows of the specific measures needed to prevent the conditions listed in table 3 but, as with antepartum care, the problem is to persuade parents to bring their children to the physician. Every physician who cares for children should practice, as a minimum, the procedures to be listed. An example of the accomplishments of postpartum preventive measures was reported by Brooks,¹⁵ who stated that in Durham, N. C., the mortality of white infants fell from 83 to 57 per thousand births and that of Negro infants from 196 to 119 during the first four years of the operation of well baby clinics.

Periodic Examinations.—Infant mortality also can be reduced if every infant is carefully and completely examined by a family physician or pediatrician immediately after birth and at intervals of one month during the first half of the first year, of two months during the second half, of four months during the second year, of six months from the third to the sixth year and annually between the ages of 6 years and puberty. After the age of 2 years every child should be seen at least twice a year by a dentist. Annually from the age of 6 years, or earlier if necessary, children's vision should be tested by having them read test figures at a distance of 20 feet; children with visual defects should be examined and treated by a competent ophthalmologist. Deafness should be investigated by an otolaryngologist. The summer round-ups of children advocated by parent-teacher associations and health departments have been very beneficial.¹⁶ Summer camps and Boy and Girl Scout activities also have greatly improved the health of children. It is just as true of children as it is of automobiles that checking at intervals and precautionary measures are more economical and more satisfactory than waiting until trouble requires repairs. If

14. A positive Wassermann reaction of the cord blood or of the infant's blood during the first week of life and even up to the seventy-third day in evidence of syphilis in the mother but not necessarily in the infant (Fildes' law). The Wassermann reaction of the cord blood usually is the same as that of the infant's blood, but only half of the mothers who have positive blood Wassermann reactions have positive cord reactions. Of the children whose cord or early blood Wassermann reactions are positive, 17 per cent do not have syphilis; another test at the age of 2 weeks usually is less strongly positive, and the reaction becomes negative at the age of 3 months. If the child has syphilis, the positive Wassermann reaction and other evidence persist. In some syphilitic newborns the Wassermann reaction may be negative up to the age of 3 months; if the child's signs or the mother's Wassermann reaction or history suggests syphilis, the test should be repeated at the ages of 3 and 6 months. These reversals are more frequent in the offspring of treated mothers. After the age of 3 months, with very few exceptions, a persistently positive Wassermann reaction in a child indicates syphilis and a persistently negative reaction excludes the possibility.

it is profitable and economical to take a Chevrolet or a Ford costing \$700 to a garage at intervals for inspection and adjustment, should not the public be educated by publicity¹ to take a child with a potential value of \$10,000, according to some estimates, to a physician for periodic examinations?

Infant Feeding.—An infant should be breast fed for the first six months. Between the ages of 8 days and 3 years all children should be given daily from two to four teaspoonfuls of cod liver oil and from two to four tablespoonfuls of tomato or orange juice, or their equivalent substances. Diseases and deaths among breast fed infants are lower than among those artificially fed.¹⁷ For weaning, evaporated (unsweetened) milk diluted with water and lactic acid and containing added sugar or Karo is digestible, safe and cheap. The use of lactic acid milk, because of its bactericidal action, has reduced the mortality from diarrhea and dysentery.¹⁸ The home instructions for its preparations are simple.¹⁹ The transition from breast or lactic acid milk feedings to a general diet should be made gradually from the fifth to the eighth month of age by adding one article of food at a time. For example, from one to four tablespoonfuls of cooked cereal should be fed once or twice daily before the bottle feedings at the age of 5 months, from one to four tablespoonfuls of finely chopped cooked meat or one egg daily at the sixth month, and so on, until by the age of 1 year the child is receiving a general well balanced diet. Every infant and child should be given as much fluid as possible, especially during hot weather. Because of their high salt content, bouillon cubes dissolved in a cup of hot water and then cooled should be given frequently during the summer.

Immunization.—At the age of 3 months infants should be vaccinated on the leg against smallpox. Reactions, complications and contaminations are less frequent at this early age. At the age of 4 months infants should be inoculated at weekly intervals with three doses of whooping cough vaccine. At the age of 9 months they should be protected against diphtheria with three doses of diphtheria toxoid or alum-precipitated toxoid at intervals of three weeks. Combined diphtheria and tetanus toxoid also is being used. Three

months later, and also annually thereafter, Schick tests should be done. If they are positive, the toxoid injections should be repeated. Unless combined diphtheria and tetanus toxoid has been given, three injections of alum-precipitated tetanus toxoid at intervals of two months are recommended at the age of 1 year.²⁰ If the child has not been thus immunized, tetanus antitoxin should be administered if severe cuts or wounds occur. Tetanus neonatorum can be eliminated by clean obstetrics and midwife control.²¹ Any one bitten by a mad dog, or one suspected of being mad, should receive the Pasteur treatment. If a child is exposed to measles, chickenpox or mumps, injections of blood from persons who have recovered from these diseases may be used. Immune globulin (human) also may modify measles. Children who live in districts in which scarlet fever is prevalent or severe can be protected against this disease if at the age of 1 year five doses of scarlet fever toxin are administered at weekly intervals and a Dick test is made two months later to determine the efficacy of the immunization. The Dick test should be repeated annually, as reimmunization may become necessary. At the age of 1 year children should be immunized with three injections of typhoid-paratyphoid vaccine at intervals of seven days. Typhoid and paratyphoid fever, though the death rate is decreasing in cities,²² still are a menace because of automobile travel and the dispensing of cold drinks in open water-filled containers, which frequently are contaminated by the hands of customers and clerks, some of whom may be carriers.²³

Deficiency Diseases.—In addition to those already cited, the other diseases listed in table 3 can be prevented. Malnutrition, nutritional and feeding disturbances, dehydration, anemia and the deficiency diseases (pellagra, rickets, scurvy, carious teeth and tetany) do not occur if the diet and amount of fluid are adequate.

Automobile Accidents.—Such occurrences are preventable, especially for children, who should be taught at home and at school to take precautions constantly.

Brucellosis (undulant or Malta fever).—This infection and other milk-borne diseases, e.g. tuberculosis, typhoid-paratyphoid A and B and streptococcal sore throat, often would be prevented by the rigid observance of the standard milk ordinance, the pasteurization of sweet milk and the use of whole lactic acid evaporated milk.¹⁸

The Spread of Dysentery and Summer Diarrhea.—This can be prevented by the following measures: the feeding of whole lactic acid evaporated milk mixtures to infants under 2 years of age; the pasteurization of sweet milk, butter and cheese fed to children; the thorough washing of the mother's or attendant's hands with soap and water every time she has been in contact with excreta of a person suffering from diarrhea of any form, or before she handles food for children; the keeping of excreta and soiled clothing of patients suffering from diarrhea in covered buckets containing soap pow-

Child.* 40:72-78 (Jan.) 1935.

19. In the preparation of lactic acid evaporated milk, the contents of a 7 cent can of unsweetened evaporated milk (390 cc., or 13 ounces) are poured into a clean quart milk bottle previously scalded with boiling water, and the empty can is nearly filled with boiling water, in which then are dissolved one teaspoonful of lactic acid (U. S. P.) and three level tablespoonfuls of sugar. As soon as this solution is cold it is poured slowly into the quart milk bottle containing the unsweetened evaporated milk, while shaking the bottle constantly. Although not necessary, it is advisable, if the lactic acid is to accomplish its full bactericidal effect, to keep the mixture six hours, preferably though not necessarily in a cold place, before it is fed in required amounts to the infant.¹⁸ It should not be boiled or pasteurized, as it will curdle. Infants of any age can be fed 100 cc. (100 calories) of this mixture per kilogram of body weight (1½ ounces [45 calories] per pound) divided into from four to six feedings. If a child requires more than this amount (one can each of milk and water, a total of 780 cc., or 26 ounces) he also needs solid food. For premature, weak and very young infants, who occasionally vomit this formula, a small 5 cent can of unsweetened evaporated milk (160 cc., or 5½ ounces) may be added to two cans of water, one teaspoonful of lactic acid and two level tablespoonfuls of sugar; the mixture then contains 67 calories per hundred cubic centimeters or 20 calories per ounce, and 150 cc. per kilogram of body weight (2½ ounces per pound) is required in twenty-four hours. A few infants thrive better on cultured whole lactic acid milk than on the evaporated variety.

der and water until they can be boiled; the screening of houses, and the use of mosquito nets for the beds of children to prevent the access of flies.

Malaria.—This can be prevented by eliminating mosquitoes, by cleaning up and draining swamps, pools and collections of standing water and by screening houses and sleeping quarters.

Poisoning.—The sale of lye and other caustics without a prominent label should be prohibited by law.²⁴ All poisons should be plainly labeled and kept out of reach of children.

Poliomyelitis.—No benefit from vaccination has been proved, but during an epidemic children under 12 years of age should avoid crowds, swimming pools and indoor contacts with other children and especially with adults, many of whom may be carriers.²⁵ The crippling effects of the disease can be greatly reduced by adequate orthopedic care, which now is available under the crippled children's program supported by the United States Children's Bureau and state health departments.

Respiratory Infections.—The death rate directly or indirectly resulting from colds and respiratory infections is appallingly high. It is essential to remember that the cause of colds, which precede more severe infections, is exposure to an infected person. The inference is plain. The child should be protected from those who are suffering from colds by minimizing exposures and the use of cotton flannel face masks. The system of allotting teachers to schools on the basis of pupil days instead of pupil enrolment increases the spread of respiratory infections because many teachers do not realize the risk in urging the attendance of children who have "just a slight cold." If these children were kept in bed at the onset of the illness recovery would be more rapid, contact cases would be avoided and the pupil days would be increased.²⁶ If the adenoids and tonsils are frequently infected, as indicated by recurring sore throats and enlarged cervical lymph nodes, they should be removed.

Tuberculosis.—Every one must be instructed not to expectorate or cough while near children or to kiss them. Any member of the family, servant, nurse or any other person who comes in contact with children should be carefully examined by x-rays for tuberculosis if such a person has a chronic cough, however mild. Tuberculosis in children can be prevented only if those who have the disease can be kept away. Women with active tuberculosis should not have children. Tuberculin tests should be made on every one. If negative, the test should be repeated annually. If positive, a physical and bacteriologic examination, and chest roentgenograms should be made so that those who have active or incipient infections may have adequate sanatorium or preventorium care. Contacts also should be examined to determine the source of the infection. Literature about this disease should be obtained from health departments and tuberculosis sanatoriums.

Mental Hygiene.—Last but not least, this is one of the most important phases of preventive pediatrics. Although not a factor in infant mortality, mental health problems, because of wrecked lives, often are as serious as those of physical health. Proper habit training, especially in eating and sleeping, child guidance and

parental education²⁷ are essential. A harmonious home and a congenial environment also are necessary; juvenile delinquency is largely a product of the home. A disorderly emotional life must be recognized and corrected as early as possible. The school load should be reduced; the average child spends thirty hours a week in school and from ten to fifteen hours in additional home work. Kindergartens should be compulsory to accustom a child to companionship. The relationship of pediatrics to mental hygiene should be as close as possible.²⁸

SUMMARY

The thirty-seven conditions which cause 56 per cent of the annual 240,000 deaths among American children can and will be prevented if the public is educated by publicity¹ to utilize the resources of the medical profession, which are already available in many communities and being established in others. Especially is this true of the measures for better antenatal and natal care.

The pediatrician must continue to lead in preventive measures and must also include mental hygiene and adolescent problems in his field.

School of Medicine, Duke University.

27. Child guidance is bettering the adjustment of children to their immediate environment, with special reference to their emotional and social relationships, to the end that they may be free to develop, to the limit of their individual capacities, to well balanced maturity. This function is exercised through the direct study and treatment of maladjusted children and the spread of the mental hygiene attitude throughout the agencies responsible for child care. Child guidance also helps the child by promoting parental understanding of and sympathy for his problems and by giving him, in the later years of childhood, a directive insight into his own behavior, thus affording a basis for the prevention of psychoses. Clinics for this purpose usually require pediatricians, psychiatrists, psychologists and social workers, but a family physician or pediatrician usually can, if as interested as he should be, produce satisfactory results. The child's past history, parents, socio-economic factors, home surroundings and school associations should be studied for emotional attitudes and evidence of adjustment and maladjustment. The child's confidence should be obtained and mental and performance tests made. Every maladjusted child has one or more problems and his behavior is an attempt to solve them. The physician's task is to learn the nature of these problems (such as fear of teachers or worry over unhappy homes) and by friendly explanation to help the child to meet them. Education of the parents in the training of children is, or should be, part of the pediatrician's duty. They should be taught to have a happy, healthy relation to the child, which will tend toward the development in him of such habits, patterns of conduct and mental attitudes that he will attain independence and normal control of his own emotions and habits. Bad habits often are developed by devoted but misguided mothers and grandparents who try to live the child's life for him. Infants should have exercising, loving care and the consistent, prompt response to their needs. However, rocking children to sleep, rubber pacifiers and evening amusements may be harmful. (Preston, M. I.: *Child Guidance in Outpatient Pediatrics*, J. Pediatr. 7: 452-464 [Oct.], 1935. Richards, E. L.: *Child Guidance Clinics*, New York, Common Behavior Aspects of Child C. 1932. L.: The Mental Hygiene of Behavior of Infants: A Pediatric Approach to the Mental Hygiene of Early Life*, J. B. Lippincott Company, 1937. Aldrich, C. A., and Macmillan, M. M.: *Babies Are Human Beings*, New York, Macmillan Company, 1938). Adolescence is one of the greatest of pediatric problems, for children at puberty are subjected to physiologic, physical and psychic changes with marked exaggeration of sex impulses and emotions, and in addition they must adjust themselves to society by going from the period of parental control through a period influenced by emotions to adult life, which is or should be controlled by reason. Mental strain should be avoided and parents should not set intellectual goals which are too high for these children. Nine hours of sleep, one hour of mild outdoor exercise, a 4,000 calorie diet for boys and a 3,000 calorie diet for girls should be insisted on, and excitement and entertainments should be minimized. Overexercise and strenuous competitive athletics are harmful during this period. The family physician or pediatrician, if he can and will spend time and thought on the psychologic and social implications involved, should instruct the preadolescent child and his parents in sex development and the transition period and in a healthy normal attitude toward it.

KARAYA GUM (INDIAN GUM)
HYPERSENSITIVITY

KARL D. FIGLEY, M.D.

TOLEDO, OHIO

To Dr. Stearns S. Bullen,¹ of Rochester, N. Y., belongs the credit of first calling attention to karaya gum as an allergen, in reporting a case of perennial hay fever from this substance. The patient was a woman, and the source of the karaya gum was the wave set material used on her hair. The following year Feinberg² reported a case of asthma due to karaya gum. Recently, through personal communication, I have learned of additional cases of sensitivity to the gum from Dr. Ralph Bowen, of Oklahoma City,³ Dr. John Mitchell,³ of Columbus, Ohio, and Dr. John Sheldon,³ of Ann Arbor, Mich. To the reported cases, I here add sixteen cases from my own practice.

Attention is again called to karaya gum because of its widespread use in wave sets, the substance having almost supplanted flaxseed, quince seed, tragacanth and acacia for this purpose. The powdered gum may be obtained from any wholesale drug house and is comparatively cheap. Skin tests are readily performed by the scratch method using the moistened gum powder or a drop of any suspected wave set material. Intracutaneous test material can be made by dissolving a few granules of the gum in buffered saline solution and then sterilizing through a Seitz filter.

In addition to inhalation of karaya gum from the flaking of dried wave set material when the hair is combed, I sometime ago discovered that symptoms could be caused by ingestion. One of my patients with perennial hay fever reported a sharp attack of atopic coryza after eating a gelatin preparation which was found to contain the gum. A little later I asked her to swallow some of the gum mixed with food (mashed potato). Within a few moments after she swallowed a mouthful of the mixture there occurred a pronounced attack of atopic coryza and considerable epigastric discomfort. The patient was careful not to inhale any of the powdered gum. As will be related, several other patients have had definite symptoms from the ingestion of karaya gum.

Some of the known sources of contact with karaya gum are presented in table 1.

In the course of routine testing with karaya gum since Bullen's first publication, I have encountered sixteen instances of hypersensitivity to the gum, all in women. In seven cases no other reactors were given. The symptoms caused were perennial hay fever (atopic coryza), asthma, atopic dermatitis and gastrointestinal distress. All patients reacted strongly by scratch test: I have found no instances of reaction to intracutaneous test where the scratch test was not positive. Passive transfer tests gave definite positive reactions to karaya gum in the four cases in which they were attempted. The family history was positive for allergy in fourteen of the sixteen cases. A brief synopsis of the cases is presented in table 2.

Karaya gum as sold commercially is a fine white powder with an odor somewhat like that of acetic acid. It is entirely soluble in water, forming an adhesive

mucilage more viscous than acacia. According to the twenty-second edition of the U. S. Dispensatory the name karaya, or Indian gum, has been applied to a number of substances, including Bassora gum, Sterculia gum and ghatti gum, which are derived from similar species of tropical trees. In India this gum is employed as a sizing agent in the calico printing industry.

In a recent article by Prof. A. C. Ivy⁴ the following statement is made relative to the nature of the gum:

Karaya gum is collected from the bark of a tree of the *Astragalus* species (*Sterculiaceae*). It is sometimes referred to as false or Indian tragacanth or *Sterculia* gum. It belongs to the general group of gums known as bassorin gums. However, complete information regarding the chemical and physical properties of karaya gum is not available in the literature. According to Pringsheim⁵ the literature dealing with the gums and mucilages is very inaccurate and conflicting. Norman⁶ states that no essential difference exists between gums and hemicelluloses; in both, hexose and pentose are linked with uronic acid. Solis-Cohen⁷ gives arabin, bassorin and cerasin as the proximate principles of gums. Gums are chiefly pentosans. Many gums and vegetable mucilages, when dry, have the property of imbibing relatively large quantities of water. Porges,⁸ using a mucilage of the bassorin type, found that it

Saraka (Sehrling)
Mucara (John Wyeth)
Imbicoll (Upjohn)
Bassoran (Merrell)

imbibed about three times more water than linseed or psyllium seed and five times as much as agar. Parsons⁹ and Klecker¹⁰ reported that the bassorin they used absorbs slightly more than two times more water than agar.

The report on the analysis made for me of two samples of karaya gum is as follows:

Sample 1. 1 Gm. of gum contains 11.45 mg. of nitrogen, 8.45 mg. of nonprotein nitrogen, 3.0 mg. of protein nitrogen and 0.0019 mg. of protein.

Sample 2. 1 Gm. of gum contains 10.44 mg. of nitrogen, 7.21 mg. of nonprotein nitrogen, 3.23 mg. of protein nitrogen and 0.002 mg. of protein.

It thus appears that karaya gum contains approximately 0.1 per cent total nitrogen.

Recently several commercial firms have marketed laxatives with karaya or some similar gum of the

bassorin type as the principal constituent. In the article by Ivy⁴ this statement appears:

Karaya was administered in the form of granules under the trade name of "Mucara" to eighty-nine graduate and medical students, nurses and social workers (forty-six were female, forty-three were male). Each subject kept an accurate account of all food and fluids taken for seven days. This diet was then repeated on the same days of the following week with the addition of one heaping teaspoonful of Mucara taken once daily

but some or all of their symptoms to the frequent ingestion of the gum. Then too I wish to stress the widespread consequences of the indiscriminate use of these bassorin laxatives by unsuspecting allergic persons. The literature advertising Mucara states that "Mucara is a useful, harmless agent for the management of simple constipation," and yet three of the four patients of mine who were given karaya gum to swallow were made ill by it.

TABLE 2.—Synopsis of Cases of Karaya Gum Sensitivity

Case No.	Patient	Age, Yr.	Family History of Allergy	Source of Contact	Chief Symptoms	Results of Test	Other Reactors	Comment
1	Mrs. E. H. M.	31	Positive	Wave set, licorice, gum drops, listerine tooth paste	Perennial hay fever, eczema of ear lobes, asthma, chronic indigestion	Cutaneous ++++ Intracutaneous ++	June grass, English plantain, cottonseed	Nausea, epigastric pain and bloating for 2 days after swallowing 2 teaspoonfuls of mucara
2	Miss L. M.	21	Negative	Agar-psylla? gum drops	Atopic dermatitis (generalized)	Cutaneous ++++ Intracutaneous ++++ Passive transfer positive	None; foods?	Nausea, vomiting, diarrhea, cramps and flare-up of dermatitis after swallowing 2 teaspoonfuls of bassorin
3	Mrs. O. A.	27	Positive	Wave set	Perennial hay fever, asthma	Cutaneous ++++ Intracutaneous ++++	Wheat, orris, flaxseed	Gum sensitivity not of major importance
4	Miss V. M.	16	Positive	Wave set	Atopic dermatitis (generalized)	Cutaneous ++++	Cereals, pollens, quince seed, cottonseed, kapok seed, flaxseed, silk	Gum sensitivity one of several factors
5	Mrs. G. C. W.	40	Positive	Wave set every week	Seasonal hay fever, perennial asthma	Cutaneous ++++	Ragweed, cat hair, house dust	Severe asthma from inhaling powdered karaya gum
6	Mrs. A. W.	36	Positive	Wave set	Asthma	Cutaneous ++++	Cat hair, shop dust	Asthma chiefly due to shop dust; polishes cutlery with flannel cloths
7	Mrs. L. D. L.	35	Positive	Wave set	Contact dermatitis, perennial hay fever	Cutaneous ++++ Intracutaneous ++	Positive patch test to fur dye	Patch test negative with karaya gum; atopic coryza from inhaling powdered gum
8	Mrs. H. C. D.	26	Positive	Wave sets, ice cream	Perennial hay fever, dermatitis of eyelids, face and arms	Cutaneous ++++ Intracutaneous ++++ Passive transfer positive Patch negative	None	Severe atopic coryza and abdominal cramps from ingestion of karaya gum

after the evening meal (9 Gm. Mucara equal approximately 7 Gm. karaya). . . . Seven, or 7.8 per cent, complained of some abdominal discomfort associated with distention shortly after taking Mucara. Three, or 3.4 per cent, complained of mild abdominal cramps while taking the Mucara.

Professor Ivy then went on to say that he was at a loss to account for the abdominal symptoms occasioned in these seven persons by the ingestion of the karaya gum. My own thought is that they were possibly mildly hypersensitive to the gum through having previously swallowed it as an ingredient of some food or confection.

I quote from Ivy's article to call attention to ingestion as a very prevalent means of contacting the bassorin gum—just as important a source as inhalation. In my series of sixteen, seven of the patients could attri-

Karaya and related gums of the bassorin type are not harmless agents but may cause severe symptoms in the allergically susceptible by inhalation or ingestion.

SUMMARY

1. Sixteen cases, in addition to those before reported, of hypersensitivity to karaya gum were observed.

2. The chief presenting symptoms were perennial hay fever (atopic coryza), asthma, atopic dermatitis and gastrointestinal distress.

3. Ingestion, as well as inhalation, is a means of contacting the allergen.

4. The indiscriminate employment of karaya gum as a supposedly harmless laxative, especially for persons susceptible to allergic sensitization, should be avoided.

THE PROTHROMBIN IN THE BLOOD OF NEWBORN MATURE AND IMMATURE INFANTS

AS DETERMINED BY THE MICRO PROTHROMBIN TEST

KATSUJI KATO, M.D.

AND

HENRY G. PONCHER, M.D.

CHICAGO

The recent phenomenal progress in the knowledge of the antihemorrhagic factor, called vitamin K by Dam and Schönheyder,¹ and its influence on the prothrombin activation of the blood have brought into clear relief the etiologic relationship in which this vitamin stands to the hitherto obscure bleeding tendency frequently encountered in the neonatal period. As early as 1912 Whipple,² after conducting coagulation experiments on the heart's blood obtained at autopsy from an infant dying of melena neonatorum, stated in no uncertain terms that the absence of prothrombin in the blood constituted the underlying cause of this disease. Simply because the blood used in Whipple's experiments was collected after death, this striking conclusion, published over a quarter of a century ago, apparently remained unheeded. Whipple, in the necropsy protocol, stated that the blood was quite fluid and that no evidence was found of any clot formation in any part of the vascular system. In retrospect it must be admitted that his conclusion, while based on observations of only two cases, was entirely logical and correct.

The more definite development of our knowledge further confirming the observation cited dates from 1929, when Henrik Dam,³ in the course of biochemical investigations on sterol metabolism in chicks, first suspected the existence of vitamin K, since in the chicks on a fat-free diet hemorrhagic manifestations frequently developed. It was not, however, until satisfactory methods for quantitative estimation of prothrombin in the blood were evolved that the important role of this vitamin in the mechanism of blood coagulation began to be appreciated. In 1935 Quick, Stanley-Brown and Bancroft⁴ improved the older Howell's method by using a suspension of thromboplastin in excess and then recalcifying the oxalated plasma. By this method Quick and Grossman⁵ measured the prothrombin concentration of the blood in a few newborn babies and reported profound fluctuations occurring during the first forty-eight hours of life. Later Brinkhous, Smith and Warner,⁶ in

developing a two stage titration procedure, actually measured the prothrombin content of the plasma and observed that the prothrombin values of the twenty-one normal infants of varying ages were generally low throughout the first year of life, particularly those of newborn babies, ranging from 14 to 39 per cent of the level found in normal adult plasma. Owen, Hoffman, Ziffren and Smith,⁷ using a simpler technic first developed by Quick,⁸ demonstrated the same low level of prothrombin content in thirty-eight normal infants with a drop between the second and sixth days of postnatal life. Dam, Tage-Hansen and Plum⁹ endeavored to account for hypoprothrombinemia in newborn infants on the basis of vitamin K deficiency due to a defective absorption of the vitamin from the gastrointestinal tract.

More recently Waddell, Guerry, Bray and Kelley,¹⁰ in a published analysis of blood coagulation studies on two newborn infants having abnormally long prothrombin clotting time, reported the pronounced shortening of the clotting time following administration of vitamin K. Waddell and Guerry¹¹ further studied twenty newborn infants with special reference to the occurrence of unnatural bleeding. These infants were divided into two groups of ten each, one group serving as controls. The infants receiving no vitamin K therapy were found to show a prolonged prothrombin clotting time between the ages of 48 hours and 72 hours, whereas in those receiving the treatment the prothrombin clotting time was consistently shorter.

In this connection it is also of interest to know whether there exists any relation between the maternal and the fetal blood with respect to prothrombin concentration. As measured by the method of Warner, Brinkhous and Smith,⁶ Hellman and Shettles¹² reported extremely low prothrombin levels in nineteen full term normal infants and nine premature infants, particularly in the latter, in sharp contrast to the normal complement of prothrombin found in their respective mothers. By administering vitamin K to some of these mothers prior to delivery they increased the plasma prothrombin from 68 to 130 per cent of control values. The normal full term babies born to these mothers also gave prothrombin levels almost three times as high as the average values found in other infants. Again, by giving vitamin K to two premature infants after birth they caused the plasma prothrombin to be elevated by the fifth day to from three to six times the initial values. Using the Quick technic, Norris and Rush¹³ reported the prothrombin values of the maternal blood at delivery to be above normal (107 and 133 per cent for the undiluted and the 25 per cent diluted plasmas) and those of the babies' blood to be below normal (77 and 62 per cent for the undiluted and the 25 per cent diluted plasmas). On repeating the determinations from seven to fourteen days after delivery they noted a slight

increase in the prothrombin values in the babies' blood (89 and 82 per cent for the undiluted and the 25 per cent diluted plasmas), while no significant changes were observed in the mothers' blood.

The studies published, though few, clearly indicate the necessity of ascertaining the normal range of vari-

venous plasma. Since this method requires only an amount of whole blood (from 10 to 15 cu. mm.) small enough to be easily obtainable from simple skin puncture, the prothrombin tests can be readily carried out several times a day on the same infant. This micro adaptation of Quick's method may be briefly described as follows:

METHOD

Whole blood obtained from a deep skin puncture made on the heel of the infant and oxalated in the proportion of 1:500, using the double oxalate mixture in dry form as elsewhere described,¹⁵ was used throughout the entire investigation. Ten cu. mm. of well mixed oxalated blood is measured out by means of a combination microhemopipet,¹⁶ and the contents are expelled carefully either on a small watch glass or into the hollow of a test plate. A suspension of thromboplastin with a potency giving the prothrombin clotting time of about twenty seconds for normal adult blood is then added in the same amount, and this is followed immediately by the addition of the same quantity of 0.025 molar calcium chloride solution. After several seconds

Chart 1.—Prothrombin dilution curves, showing a close correlation between the curves obtained by micro prothrombin test and that published by Quick.

ations in the prothrombin concentration of a large number of both mature and immature infants. The chief obstacle in undertaking an investigation of any magnitude in newborn infants is the difficulty of applying prothrombin methods, which require relatively large amounts of venous blood. Venipuncture in small infants necessitates entering either the superior longitudinal sinus or one of the jugular (external and internal) veins, a procedure which, while perfectly harmless in the hands of experienced workers, nevertheless is not

Chart 2.—Scattergram representing 894 tests of the prothrombin clotting time of 100 mature infants from birth to the eleventh day of life.

practical if the tests are to be performed at frequent intervals on the same infant. For this reason a new micro prothrombin method (Kato) was devised, following the general principle involved in Quick's original method¹⁴ but using the whole capillary blood instead of

Chart 3.—Scattergram representing 701 tests of the prothrombin clotting time of seventy-three premature infants from birth to the twenty-ninth day of life. Note marked fluctuations in prothrombin time in this group.

of thorough agitation of the ingredients by means of a fine glass rod, the prothrombin clotting time is determined with a stop watch, computation starting with the time when the last ingredient is added and ending with the fixation of the mass by fibrin formation. Since the test is carried out at average room temperature, all reagents used must also be kept at this temperature. If the reagents are used at refrigerator temperature or at any temperature below that prevailing in the room, the prothrombin clotting time will be materially prolonged. The potency of the thromboplastin suspension may vary from time to time, and hence it is advisable first to determine the prothrombin time of normal adult whole blood and then to use the value so obtained as the basal level. Since prothrombin clotting time is greatly influenced by the potency of thromboplastin, it is absolutely essential to prepare the suspension strictly in accordance with the instructions elsewhere given, using the brain of a freshly killed animal.

14. Kato, Katsuji: Microprothrombin Test with Use of Capillary Whole Blood: A Simplified Modification of Quick's Quantitative Method, *Am. J. Clin. Path.*, to be published.

As determined by this method the prothrombin clotting time of normal adult capillary whole blood under optimal conditions is twenty seconds, with deviations of plus or minus two seconds. Since the test measures not the actual amount of prothrombin but rather the clotting time according to this particular coagulation

Chart 4.—Average values for prothrombin clotting time in mature and immature infants during the first eleven days of life. Cases with abnormally prolonged prothrombin time (over two minutes) have not been included in calculating these figures.

system, the "concentration" or "level" of prothrombin in the blood in the discussion of our data refers only to the results of computation based on the prothrombin dilution curve shown in chart 1.

Comparison of curves obtained by this method of using plasma prepared according to the method of Quick and oxalated whole blood reveals a satisfactory correlation of results. Because of the presence in it of blood cells which displace a corresponding proportion of plasma, whole blood naturally contains less prothrombin than plasma when the two are compared volume for volume. Thus it is reasonable to find the prothrombin time of plasma to be consistently shorter than that of whole blood. The clinical significance of the prothrombin time lies, however, not so much in the result of a single test, unless grossly abnormal, as in the trend of changes that ensue under various conditions. These curves also compare favorably with the prothrombin dilution curve reported by Quick,¹⁷ in which the shorter prothrombin time results chiefly from the effect of the higher temperature (37 C.) at which his test is carried out.¹⁸

Recently some investigators¹⁹ have found the optimal concentration of calcium chloride solution to produce the minimum prothrombin clotting time, by Quick's method, to be that of normal blood (0.0025 molar). But shortening of the time is disadvantageous in that the percentage of error becomes greater as the clotting time is shortened.

17. Quick, A. J.: The Nature of the Bleeding in Jaundice, *J. A. M. A.* 110:1658 (May 14) 1939.

18. Interpretation of results obtained by various methods may be facilitated if the data expressed in absolute number of seconds are converted into relative number (prothrombin index) by using the equation:

$$\frac{\text{Prothrombin time of unknown blood}}{\text{Prothrombin time of normal adult blood}} = \text{Prothrombin index}$$

Under normal conditions this index is always unity, and values greater than 1.0 have longer prothrombin clotting time (low prothrombin concentration) and those less than 1.0 shorter prothrombin clotting time (high prothrombin concentration).

RESULTS AND COMMENT

The present investigation was undertaken to determine the normal limits of prothrombin clotting time in the neonatal period as tested by the micro prothrombin method just described. A total of 173 newborn infants form the basis of our study. An aggregate of 1,595 prothrombin tests were made in duplicate at frequent intervals beginning on the day of birth and continued for varying periods up to four weeks. Using the customary figure of 2,500 Gm. of body weight as the division line, the infants studied may be classified into two groups, according to the degree of maturity at birth. By this criterion 100 infants were mature and seventy-three immature. The data are presented in terms of the actual number of seconds required for the clot formation in the coagulation system recommended for the test. The prothrombin clotting time in the mature infants was studied up to the eleventh day of life (chart 2), while in the immature group the observations covered much longer periods, in a few cases extending up to the age of 4 weeks (chart 3). When these data are averaged for each date of postnatal life we obtain the general average range of prothrombin time of newborn infants during the periods here studied (chart 4). There appears to exist no correlation between the degree of infants' maturity and the prothrombin convertibility of the blood, at least on the first day of life (chart 5).

From the data presented it is at once evident that the prothrombin clotting time of the blood of newborn infants is for the most part high, particularly on the first day of life, showing an average of 46.5 seconds for the premature and 43.2 seconds for the mature infants. This prolonged prothrombin time gradually improves as the infants grow older, so that by the end of the ninth or tenth day it averages twenty-five seconds

Chart 5.—Lack of correlation between birth weight and prothrombin clotting time.

in the full term, mature babies. In the premature group the same general rule holds, although among these infants there is a tendency for the prothrombin time to show much greater fluctuations than in the mature group. Also with many immature babies the prothrombin curve, instead of describing a gradual and uniform descent, frequently rises abruptly, pointing to

a lack of stability either in the prothrombin or in the prothrombin-antithrombin equilibrium. Some immature infants, on the other hand, may show unusually rapid activation of prothrombin in the blood, as evidenced by short clotting time even on the first day of life. Some typical examples of various prothrombin curves in individual babies are shown in chart 6.

The factors entering into the convertibility of the prothrombin are undoubtedly numerous. The most important single factor is probably the action of the antithrombin of the blood. Under normal conditions the antithrombin factor is physiologically balanced by the presence of proper amounts of thromboplastin. Also important in influencing the speed with which fibrin is formed are the quantity and reactivity of the fibrinogen. Likewise calcium undoubtedly plays a paramount role in blood coagulation. All these factors must be evaluated in order to interpret properly results such as have been presented.

The specific factors influencing the level of prothrombin in the blood are also of particular clinical significance. While the exact manner in which vitamin K acts on the concentration of prothrombin is not

encing our data. Further studies on the prophylactic use of antihemorrhagic vitamin by pregnant women are in progress.

The most important clinical significance revealed by the present study is the fact that the average newborn infant possesses a smaller fraction of prothrombin complement than an adult. This explains in a most satisfactory way the exact pathogenesis of hemorrhagic disease of the newborn, clinically known as melena neonatorum, in which the chief manifestation is frank hemorrhage from the mucous membranes of the gastrointestinal tract, genito-urinary surfaces and umbilical cord. In many of the patients suffering from this disorder who came under our observation the blood prothrombin was usually demonstrated to be below 10 per cent of the normal adult complement, giving a greatly prolonged prothrombin clotting time or none at all. A detailed study of these cases will be published in a subsequent report. Again, in certain cases of intracranial hemorrhage occurring at birth it is very likely that trauma or difficult labor may play only a provocative role, the fundamental factor being a reduced prothrombin convertibility of the blood, a condition which naturally renders the patient susceptible to severe bleeding on the slightest provocation. Recently autopsy in a fatal case of intracranial hemorrhage disclosed an extensive extravasation in the posterior fossa; but a prothrombin test of the blood of this infant performed several hours before death showed complete failure of the coagulation system. This and other observations we have made emphasize the great importance and desirability of determining the prothrombin clotting time of every newborn infant; or, if this is not possible, adequate prophylactic measures should be instituted as a precaution before the infant is born. The micro prothrombin method used in the present study has been found to be entirely suitable for general and routine use, indicating that all subclinical cases of prothrombin deficiency can be recognized early and at once properly treated. Since it is not possible by antepartum examination of the maternal blood to detect which infants will have a prothrombin deficiency, the administration of vitamin K to the mother shortly before delivery is suggested.

Chart 6.—Various types of prothrombin curves in individual babies.

clearly known, it is now generally agreed that intestinal absorption of this vitamin and normal functioning of the liver are the essential requirements for maintenance of a normal prothrombin level in the blood. Thus any pathologic changes produced either in the gastrointestinal tract or in the liver theoretically will, and actually do, diminish blood prothrombin, as evidenced by the fact that many types of liver diseases and intestinal disorders are often associated with a bleeding tendency. In one premature infant in our series showing prolongation of prothrombin time for many days, strangulated hernia developed. The hemorrhagic diathesis frequently developing in patients with obstructive jaundice has a slightly different pathogenesis in that the absence of bile in the intestine interferes with the normal absorption of antihemorrhagic vitamin.

Another possibly significant factor which may be responsible for the generally prolonged prothrombin time of the blood in the infants we have studied is the dietary habit of the mothers, a majority of whom came from families of the lower social strata. While no direct attempt was made to determine the possible vitamin K deficiency in the diet of these mothers, it is probable that this might have been an important factor influ-

SUMMARY AND CONCLUSIONS

The prothrombin clotting time of 173 newborn infants, both mature and immature, has been determined by the micro prothrombin method; an aggregate of 1,595 tests were made during the neonatal period, extending over four weeks of postnatal life.

The average prothrombin time of 100 mature infants on the first day of life was found to be 43.2 seconds; gradually shortening as the infants grew older, by the tenth day of life the average time was twenty-five seconds.

The average prothrombin time of seventy-three premature infants was 46.5 seconds on the day of birth and showed a much greater degree of fluctuation on subsequent days than that of mature babies. Also in this group were some infants whose prothrombin time actually increased after birth, and in one instance the prolonged prothrombin time of the blood was associated with strangulated hernia.

No correlation was found to exist between the degree of the infant's maturity and the prothrombin clotting time of the blood, at least on the day of birth.

The low prothrombin level of the blood in newborn infants satisfactorily explains the pathogenesis of

hemorrhagic disease of the newborn. This may be expressed clinically as hemorrhage into the gastrointestinal tract (melena, hematemesis) or bleeding from the cord (omphalorrhagia) or genito-urinary tract (hematuria). While in some cases of intracranial hemorrhage birth trauma was the precipitating factor, the severity of the bleeding was apparently induced by a lowering of the prothrombin level of the infant's blood.

LIESEGANG AND MUSCLE PRESSURE WAVES

EFFECTS OF MICROCAPILLARITY ON MICROCOMPRESSIONAL WAVES OF PHYSIOCHEMICAL CHANGES CAUSING LIESEGANG AND MUSCLE STRIAE

EBEN J. CAREY, M.D.

MILWAUKEE

The structural significance of the cross striae and their relationship to the function of skeletal and cardiac muscles are unknown, even though the problem has been investigated for more than a hundred years. The factors resulting in the formation of periodic stratification in gels of concentric rings and spirals in agate and gelatin (Liesegang,¹ Hardy,² Ostwald³ and many others) and the periodic bands in specially prepared gelatin in films and cylindrical columns in test tubes (Hatschek,⁴ Bradford,⁵ Küster,⁶ Hughes⁷) are still under investigation. Recently Raman and Subbaramiah⁸ and others have presented evidence that the Liesegang phenomenon may be interpreted in terms of a wave effect. No experimental attempt heretofore has been made to study comparatively the microscopic striations produced in specially prepared gels in microcapillary glass tubules and the cross striae of muscle. Evidence is presented that there is an underlying physiochemical wave mechanics in the production of both Liesegang and muscle striae.

My objectives in this paper are (1) to demonstrate variable wave patterns and wavelengths expressed as striae that accompany different chemical changes in gelatin when the reactions are concentrated and transmitted within the lumen of a microcapillary glass tubule, (2) to compare these microscopic Liesegang striae with those found in striated muscle under controlled experimental conditions and (3) to suggest the significance of this concept of wave mechanics in the normal and

abnormal motions of muscle, as previously suggested,⁹ during the transformation of chemical into mechanical energy.

METHODS

Transverse and spiral Liesegang striations are generated by the simple method of confining from 4 to 10 per cent gelatin plus either 0.5 to 1 per cent sodium chloride, sodium iodide, sodium bromide or potassium bichromate within microcapillary glass tubules from one-half to 2 inches long, with an inside diameter of from 25 to 100 microns. The tubules are then placed in from 5 to 10 per cent silver nitrate for from fifteen minutes to twelve hours, mounted on microscopic slides by sealing the tips with melted paraffin. Evanescent striae, which last from thirty minutes to one hour, are produced when 10 per cent gelatin plus 2 per cent uric acid dissolved in 2 cc. of 0.1 per cent solution of sodium hydroxide are confined in microcapillary tubules to the ends of which is placed 10 per cent hydrochloric acid (fig. 3). Many other inorganic and organic chemical reactions are studied in a similar manner in more than 1,000 microcapillary glass tubules, including those of living anebas, in which a cross striated orientation of the living granules can be periodically demonstrated.

Living intact rectus abdominis muscles of the skinned frog (*Rana pipiens*) were stimulated by sudden elevation in temperature from 20 to 37 C. for ten seconds, then depression to 4 C. for fifteen minutes, and also by mechanical stretch, electrical and various chemical means. The animals are quickly frozen for six hours and then placed in 10 per cent formaldehyde U. S. P. for twenty-four hours; the muscles are excised, embedded in paraffin, serially sectioned, mounted on glass slides and stained with hemalum and eosin. Directly controlled observations of the changes within the intact living muscle fibers are made with the ultra-paque microscope and water immersion lenses.

Traveling overlapping peristaltic waves in both the intact intestine and the pregnant uterus with normal intact blood supply in the living guinea pig are converted into a standing system of pressure waves by tying ligatures from one-half to 1 inch apart prior to stimulation by any one of the following means: the direct application of 1 per cent pilocarpine, acetyl choline, barium chloride crystal, mechanical stretch or electrical stimuli. Multiple reflections of the intestinal waves between the two ligatures result in a standing system by constructive interference.

RESULTS

Liesegang striae from 0.5 to 35 microns apart (fig. 1A) are found in the microcapillary glass tubules which contain silver iodide and from 4 to 60 microns in those with silver chloride (fig. 1D). The striae are finer and closer together near the ends of the tubule, where the diffusing silver nitrate is higher in concentration and where the frequency of reversible mass action of chemical change is greater than that in the middle of the tubule between the two ends.

Striae in muscle fibers subjected to sudden rise in temperature to 37 C. (fig. 1B) and those from mildly

contracted muscle (fig. 1 *C*) at 15 C. are different in number in the fiber. Strongly contracted muscle has multiplication in the number of cross striations and rounded condensed nuclei (fig. 1 *B*) in contrast to those in the weakly contracted fiber. Reduction in the rate of chemical change by inducing hibernation through artificially cooling frogs and honey bees at 8 C. for from one to three weeks results in a progressive loss of cross striae in the muscle fiber. The muscle striae reappear when the temperature is raised to 20 C. within one to five hours. In irreversible strong muscle rigor the changes may be so great in parts of the muscle that the cytoplasm is arranged in homogeneous broad bands like Zenker's degeneration with the fine striae invisible. Phase amplitude and length differences in the underlying wave mechanics is microscopically detected by differences in the width and splitting of striae (figs. 1 *C* and 2 *B*). A vernier shifting effect of the muscle striae (fig. 1 *C*) and those striae of silver chloride (fig. 1 *D*) is evident. This may be due either to a spiral arrangement of striae or to a slight shifting of the wave front.

Fig. 1.—*A*, gelatin silver iodide striae within microcapillary glass tubule, inside diameter, 80 microns; reduced from a photomicrograph with a magnification of 260 diameters. *B*, strongly contracted muscle fiber, rectus abdominis of frog, compressed nuclei, fine striae with periodic beats of compact striae; original magnification 780. *C*, mildly contracted muscle fiber, rectus abdominis of frog, long nuclei, wide variable striae; original magnification 780. *D*, gelatin silver chloride striae within capillary glass tubule, inside diameter 80 microns; original magnification 260. Vernier shift of striae in *C* and *D*.

The spirality is the result of two simultaneous motions of the wave front: (1) translation and (2) rotation. Not all Liesegang and muscle striae, however, have a spiral arrangement.

A superpositional wave effect is detected (fig. 2 *A*) when silver iodide and chloride are produced simultaneously within the same microcapillary glass tubule. A fine dark band is frequently found in the middle of the light one (fig. 2 *A*), giving the effect observed at

Fig. 2.—*A*, superposed gelatin silver iodide and chloride striae within capillary glass tubule, inside diameter 100 microns; original magnification 260. *B*, strong contraction waves with pressure nodes, fine striae, compressed nuclei; tension internodes, wide striae, long nuclei of rectus abdominis muscle fiber of frog; original magnification 910. *C*, compressed nodal, stretched internodal nuclei, long muscle layer, colon of guinea pig; original magnification 260. *D*, superposed gelatin silver iodide striae within capillary glass tubule, inside diameter 80 microns; original magnification 260.

times in muscle (fig. 2 *B*) of the alphabetical series of alternate dark and light Q, J, Z, J, Q bands. The intermediate Z band is inconstant in striated muscle. It is not a sine qua non of genuine cross striated muscle (compare figs. 1 *C* and 2 *B*). The Z band appears at a certain energetic level of the intrinsic wave mechanics of muscle.

Strong serial contraction compression waves in frog muscle may be generated by sudden direct changes of temperature resulting in alternate nodes and internodes (fig. 2 *B*). The pressure nodes have condensation of cytoplasm, fine closely spaced striae, increased anisotropy and mineral ash content and round compressed nuclei; the tension internodes have rarefied fibrillated cytoplasm, widely spaced striae, decreased anisotropy and mineral ash content and elongated nuclei. Strong serial standing compression waves in the smooth muscle of the intestine (fig. 2 *C*) and pregnant uterus of the living guinea pig are generated by stimulation of the muscle between ligatures placed 1 inch apart. Pressure

nodes and tension internodes in smooth muscle are similar to those in striated muscle as regards mineral content, anisotropy and nuclei. This histologic picture becomes clear when the traveling smooth muscle waves are transformed into those of a standing system by multiple reflections, producing constructive interference between the ligatures.

When a compressional wave front travels in the direction of the arrows (fig. 2D) in a microcapillary glass tubule containing gelatin, sodium iodide and diffusing silver nitrate, there are generated superimposed intense waves. The widely spaced dark bands are generated by the photochemical action of carbon arc light for three seconds (the L's in figure 2D); the finer intermediate striae develop during the two minute interval in the dark (the D's in figure 2D). The progressive increase in the width of the dark bands with their convexities directed toward the left is due to the fact that those on the left are exposed to light over a longer period of time by the summation of the time intervals during exposure to light.

Fig. 3.—Same glass tubule containing gelatin, uric acid and diffusing hydrochloric acid (A) near end and (E) at middle of tubule. Progressive increase of wavelength with weakening of pressure wave front, identified as a transverse clear advent moving wave; original magnification 260.

The rate of travel of the mildly explosive pressure wave front (fig. 3) and the wavelength of the striae vary by changes of light, temperature, chemical concentration and constitution, colloidal state of the gelatin, length and diameter of the microcapillary glass tubules, and distance from the ends of the glass tubule. The interference pattern of the striae vary as centers of

intense photochemical reactions occur in silver chloride gelatin within the glass tubules which produce biconcave, biconvex or crisscross arrangements (figs. 4B and C). These pictures are similar to those of muscle striae underlying motor end plates (figs. 4D and E).

Fig. 4.—Gelatin silver chloride striae; A, vernier shift; B and C (original magnification 200), radiation of striae from center of photochemical change compared with similar radiation of muscle striae under motor end plates, intercostal muscle of white rat, D and E (original magnification 910), gold chloride technic.

SUMMARY

Microcapillarity confines, stabilizes, orients and concentrates the multiple microcompressional waves of physiochemical changes into alternate zones of condensation and rarefaction, expressed as both Liesegang and muscle striae. Wavelength, spacing of striae and rate of physiochemical change appear to be interrelated. Transformation of chemical into mechanical energy of muscle motion appears to be an algebraic summation of multiple micromechanical compressional waves of mildly explosive pressure, radiated from physiochemical reactions constrained within the microcapillary muscle fiber or fibril.

The Boy.—Among the golden words of the English language are those in Captain Scott's farewell letter to his wife: "Make the boy interested in natural history if you can; it is better than games; they encourage it at some schools. I know you will keep him in the open air. Above all, he must guard and you must guard him against indolence. Make him a strenuous man." —Harris, H. A.: *The Anatomical and Physiological Basis of Physical Training*, *Brit. M. J.*, Nov. 11, 1939.

Clinical Notes, Suggestions and New Instruments

SULFANILAMIDE CYANOSIS RELIEVED BY NICOTINIC ACID

J. FRANK DOUGHTY, M.D., TRACY, CALIF.

Cyanosis occurring during the administration of sulfanilamide is so common that it is expected, but it has not been considered harmful. However, other symptoms which may be distressing are the frequent headache, weakness and nausea. In my limited experience, these symptoms are rarely present without the appearance of cyanosis.

In June 1939 I was administering sulfanilamide to a patient with facial erysipelas with excellent results in reducing the temperature and activity of the lesions; but severe cyanosis, headache, nausea and vomiting occurred. I recalled having read an abstract of an article reporting the relief of symptoms with sulfanilamide by giving nicotinic acid.¹ Therefore, I administered 20 mg. of nicotinic acid three times a day. The headache and nausea stopped and the cyanosis disappeared. It was possible to continue the sulfanilamide until the erysipelas was cured.

Since that time I have administered nicotinic acid to every patient receiving sulfanilamide who developed cyanosis or any of the other signs of toxicity to that drug. Complete relief of those symptoms usually occurred. These cases have included gonorrhea, streptococcal infection of the throat and of the hands, and one case of streptococcal pneumonia.

This report is made in the hope that it may give a clue to the mechanism of the cyanosis, which some physiologic chemist may discover. Perhaps a trial of the method in a larger series of cases may be of value to many patients having symptoms of toxicity accompanied by cyanosis due to the administration of sulfanilamide.

231 West Eleventh Street.

MODIFIED WESTERGREN SEDIMENTATION TUBE

H. D. FURNISS, M.D., NEW YORK

The sedimentation tube is a modification of the Westergren tube and was designed to improve and facilitate the technic of blood sedimentation.

The tube is 250 mm. long, with an internal diameter of approximately 2.5 mm. It is graduated from zero to 200 mm. and has a capacity in the graduated area of approximately 1 cc.

Two styles are available: one with stopcock permanently attached and the other without stopcock but with a metal plug to seal the top of the tube. A separate stopcock is available for the latter. The upper end of the stopcock has a Luer slip so that any syringe with a Luer tip can be attached. A Luer-Lok syringe is recommended because the tip is much stronger. The smaller the capacity of the syringe, the better the control.

TECHNIC

From 1.5 to 2 cc. of the blood is withdrawn into a test tube containing a suitable anticoagulant solution. Three satisfactory solutions are in common use:

1. A 20 per cent solution of potassium oxalate, one drop of this being used for each cubic centimeter of blood.
2. Heparin, containing 15 cat units per milligram, one drop being used for each cubic centimeter of blood.
3. Citrate, 0.25 cc. of a 3.8 per cent solution, added to 2.25 cc. of blood.

1. McGinty, A. P.; Lewis, G. T., and Holtzelaw, M. R.: Symptoms Occurring with Sulfanilamide Relieved by Nicotinic Acid, *Georgia M. A. J.* 28: 54 (Feb.) 1939; abstr. *J. A. M. A.* 112: 1996 (May 13) 1939.

These tubes are manufactured by Becton, Dickinson & Co., Rutherford, N. J.

Blood is added to the preferred solution and the contents of the test tube are agitated gently until thoroughly mixed.

With the stopcock open and the syringe attached and in the closed position, the lower end of the tube is immersed in

Fig. 1.—Showing blood being drawn into the tube. When proper level is attained the stopcock is closed and the syringe removed.

the solution and the liquid aspirated to the zero mark. The stopcock is closed and the syringe detached.

The tube is then hung on the metal rack, which has previously been attached in a suitable place. The metal collar on the top of the tube is slotted to permit the tube to hang vertically and also prevents the tube from slipping down.

When the type with the detachable stopcock is being used, and in the event that it is desirable to use more than one tube, the bottom of the tube can be momentarily closed with the tip of the finger while the stopcock is being detached and the special metal plug, slightly moistened, is inserted in its place. If this method is used, it is suggested that the fluid level in the tube be raised slightly to compensate for the amount displaced when the metal plug is inserted into the top fitting of the tube. The finger may then be removed and the tube hung on the rack.

The glass tube can be sterilized by boiling or by the use of alcohol or the like. To avoid removing the lubricant, neither alcohol nor any grease solvent should come in contact with the stopcock.

54 East Sixty-Second Street.

Fig. 2.—Tubes on the left have integrally attached stopcocks. The ones on the right are stoppered with a smoothly fitting plug that prevents leakage.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE THERAPY OF DROPSY

H. M. MARVIN, M.D.
NEW HAVEN, CONN.

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

Dropsy, or edema, is usually defined as the accumulation of serous fluid in the intercellular spaces of the subcutaneous or deeper tissues and in the serous cavities. The source of this fluid is the blood, from which it has escaped by passage through the walls of the blood vessels. Edema is always but one manifestation—although sometimes the most dramatic and important—of some abnormality or disease process, and its removal by medical means should logically begin with treatment of the causative process. Specific measures for its removal are necessary only if its location or extent render it harmful or uncomfortable to the patient and should ordinarily be employed only after correction or treatment of the underlying abnormality.

There are many conditions with which edema may be associated, but only a few of these will be considered in this review, which is concerned primarily with the practical aspects of medical treatment. The conditions to which attention will be devoted comprise congestive heart failure, acute and chronic nephritis, cirrhosis of the liver, the Pick syndrome of constrictive pericarditis, vitamin deficiency and marked lowering of the protein content of the blood plasma, whether this is found in malnutrition, in chronic glomerulonephritis or in so-called lipid nephrosis.

For a clearer understanding of the discussion that follows, it is desirable to review briefly the mechanisms involved in the formation of edema. The opinion first expressed clearly by Starling¹ in 1896 has received the almost unanimous support of investigators in recent years; in its simplest form it may be stated as follows: The capillary wall is a membrane freely permeable to water and to most of the crystalloids of the blood, such as salt, sugar and urea, which pass from the capillary into the surrounding tissue spaces, or from these spaces into the capillary, in response to physical laws now well understood. The most important factor causing movement of fluid out of the capillary is the pressure exerted on it; in other words, the intracapillary blood pressure. If this were unopposed, most of the fluid of the blood would readily pass into the tissue spaces. But it is opposed, as Starling first showed, by a force due to the presence of proteins, chiefly albumin, in the blood plasma. These protein substances cannot pass readily through the capillary wall; by remaining within the lumen they attract fluid powerfully through the process of osmosis, the force so exerted being known as the colloid osmotic pressure of the plasma. Obviously

the direction and extent of movement of fluid through the capillary wall must depend on the balance of these two opposed forces; if the intracapillary pressure is higher than the colloid osmotic pressure, fluid will pass out of the blood stream and edema will form. On the contrary, a rise in the colloid osmotic pressure above the capillary blood pressure will result in prompt withdrawal of fluid from the tissue spaces into the blood.

It is thought that both these processes are operating continuously in health and in disease. It is impossible to assign any constant value for the capillary blood pressure, since this varies in different parts of the body and in response to many influences, but in the capillaries at the base of the finger nail Landis² has found that the pressure at the arterial end of the loop averages about 43.5 cm. of water, while the colloid osmotic pressure is about 34 cm. of water. The result of this difference is to force fluid from the capillary. But when the blood reaches the venous end of the loop the pressure has fallen to an average value of 16.8 cm., while the colloid osmotic pressure has risen because of increased concentration due to loss of water. At the venous end of the capillary, then, fluid will be drawn from the tissue spaces into the blood. It is therefore clear that edema may result from either or both of two changes: an increase in the capillary pressure or a decrease in the amount of protein in the blood plasma.

This statement has been purposely simplified and abbreviated but is essentially correct. The mechanism that it describes is not the only one concerned in the formation of edema but is generally regarded as the most important. The other primary and contributory factors have been lucidly reviewed by Landis,³ whose studies of the capillary circulation have added greatly to our knowledge. He regards as other primary factors injury to the capillary wall, which increases its permeability and obstruction to lymph channels. As contributory factors he mentions low tissue pressure, high salt intake, high fluid intake, a warm environment and disturbances of innervation. It is well to emphasize that the contributory factors may become of great importance and may actually determine the occurrence or disappearance of edema.

Thus in the capillary bed there are two important and opposed physiologic processes involved in the formation of edema; similarly in the kidney there are two fundamental and opposed processes involved in the formation of urine. It is now believed that the renal glomerulus acts essentially as a filter; relatively enormous quantities of a protein-free ultrafiltrate normally pass through it into the tubules, where most of it is reabsorbed, leaving only a small percentage to be excreted as urine. It is apparent that the volume of urine may be increased by either or both of two processes: an increase in glomerular filtration or a decrease in tubular reabsorption.

With this brief outline of the more important mechanisms in mind, we may consider the treatment of edema associated with various clinical conditions.

CONGESTIVE HEART FAILURE

Congestive heart failure is the most frequent cause of edema sufficient to require treatment; fortunately it is also the condition in which specific treatment is most gratifying. The edema is thought to be due to several

From the Department of Internal Medicine, Yale University School of Medicine, and the New Haven Hospital.

2. Landis, E. M.: Micro-Injection Studies of Capillary Blood Pressure in Human Skin, *Heart* 15: 209 (May) 1930; Capillary Pressure and Capillary Permeability, *Physiol. Rev.* 14: 404 (July) 1934.
3. Landis, E. M.: The Passage of Fluid Through the Capillary Wall, *Am. J. M. Sc.* 192: 297 (March) 1937.

factors, which probably vary in relative importance in different cases. The effective filtration pressure in the capillaries is increased by the rise in general venous pressure that occurs in congestive heart failure and also by the muscular inactivity that generally accompanies it.⁴ In addition there is increased permeability of the capillaries to water and crystalloids, and in some cases there is a fall in the effective colloid osmotic pressure of the plasma because some protein passes into the tissue spaces. The hypoproteinemia is probably increased at times by the loss of albumin in the urine and by the low protein diet often prescribed by the physician.

A detailed discussion of the treatment of congestive heart failure is beyond the scope of this article, but it is now generally agreed that this should include complete rest in bed, necessary sedatives, limitation of fluid and of salt intake, and full digitalization. These measures should precede the use of diuretics in most instances, since they will often result in marked diuresis and render further treatment unnecessary. But there are several important exceptions to this statement. If there is considerable fluid in one or both pleural cavities it should be withdrawn at once by means of paracentesis, for such fluid often causes great respiratory discomfort and is but slowly absorbed and excreted, even when diuretics are employed. Furthermore, if the edema elsewhere is so extreme as to be the cause of danger or grave discomfort, the mercurial diuretics should be administered at once, without waiting for the effect of digitalis. I am in agreement with Thomson⁵ that the diuretic effect of these agents is often just as great without digitalis as with it, and the patient may be spared some days of discomfort if they are used immediately.

Xanthines.—Until about fifteen years ago the xanthine diuretics, sometimes known as the purine bases, were the only ones in general use. For practical clinical purposes this group may be regarded as consisting of the theophylline and theobromine with their derivatives; caffeine is also a member but has little or no value as a diuretic in disease states. Theophylline may be administered in gelatin capsules containing from 3 to 5 grains (0.2 to 0.325 Gm.) and may be given two or three times a day. Even in this small dosage, however, it often causes nausea and vomiting after four or five doses have been given and must then be discontinued. Because of the likelihood of vomiting, it is usually wise to give theophylline for periods of only a few days at a time, even if it is well tolerated; there is some evidence that the total diuretic effect is greater with intermittent than with continuous administration. It is the most potent of the xanthine diuretics but can seldom be given in effective dosage because of its unfortunate side actions. In recent years it has been used far more frequently in combination with other salts, the best known preparations being theophylline with sodium acetate and theophylline with ethylenediamine (aminophylline). These are usually tolerated better than is theophylline alone and can therefore be used for longer periods, but it is well to omit them for a few days after a period of brisk diuresis. Theophylline with sodium acetate is available in tablets containing from 2½ to 7½ grains (0.16 to 0.5 Gm.); those which have an enteric coating are better tolerated by most patients. The therapeutic dose should be deter-

mined in each case by actual trial, starting with small amounts in order to avoid the induction of vomiting. Total daily quantities of from 15 to 30 grains (1 to 2 Gm.) can be taken by many subjects without discomfort if given in three or four doses, but amounts less than this often cause satisfactory diuresis. The other preparation, theophylline with ethylene diamine, is better known today because of its widespread use in recent years for its supposed effect on the coronary arteries. It is not a potent diuretic but may be of value in preventing the reaccumulation of edema that has been successfully removed by other agents. It is marketed in tablets containing 1½ grains (0.1 Gm.), and six or eight of these a day are required in most cases for any significant diuretic effect. Like other theophylline preparations, this also may cause nausea if given in doses sufficiently large to increase the volume of urine.

The Council on Pharmacy and Chemistry makes the following statement concerning the actions and uses of xanthine derivatives:

Actions and Uses.—The Council recognizes no therapeutic claim for any xanthine derivative beyond those for diuretic action and for use as a myocardial stimulant. Theobromine and theophylline surpass caffeine in their diuretic, and perhaps in cardiac and muscular, actions. They are therefore generally preferred in cardiac edemas, etc., since they are equally, or more, effective, more prompt and largely avoid the unpleasant side effects (insomnia, nervousness, gastric disturbance) which often interfere with the use of caffeine in adequate doses. This freedom from side effects holds true, particularly for theobromine. Theophylline surpasses theobromine in diuretic efficacy, but its action is probably not so lasting; it may produce gastric disturbances; renal irritation has been reported. Theobromine is therefore generally preferred, sometimes preceded for a few days by theophylline. If central stimulation is desired, caffeine must be used.

It has been the experience of almost all observers that theobromine and its compounds are less powerful diuretics than the closely related substances just named, but they are often well tolerated in effective dosage and may therefore prove to be far more satisfactory. Theobromine may be administered in capsules in doses of 5 or 10 grains (0.325 or 0.650 Gm.) three times a day and continued for a number of days if nausea does not occur. One of its best known compounds is theobromine with sodium salicylate, which contains approximately 50 per cent theobromine. This is one of the mildest of all diuretics, seldom causes nausea or vomiting and must be given in doses of from 40 to 60 grains (2.6 to 4 Gm.) or more a day. Another preparation is theobromine calcium salicylate, or theocalcin, which is said to contain 48 per cent theobromine, 11 per cent calcium and 38 per cent salicylic acid. Stewart's⁶ study indicated its advantages, and these have been confirmed by subsequent experience. It is a potent diuretic, often superior to theophylline in this respect, seldom causes nausea and may be continued without intermission as long as diuresis results. It is available in tablets containing 7½ grains (0.5 Gm.), and the usual effective dose is from three to six tablets a day; larger amounts may be given if necessary.

It is the belief of many students that the xanthines cause diuresis by an action on the renal glomerulus, increasing the filtration, but authoritative opinion is not agreed on this. Smith⁷ states that, although they increase the filtration rate, this is not an essential factor

in their diuretic action, which is to be attributed to diminished reabsorption of water in the tubules. A final statement on this point is not possible as yet. The xanthines as a group are far from negligible; in recent years they have been overshadowed and to a large extent superseded by the mercurials, but they have an important place in the treatment of patients with slight or moderate edema and of those patients who object seriously to intravenous injections.

Organic Mercurials.—The mercurial diuretics are unquestionably the most effective available today, even though an occasional patient may exhibit a greater response to one of the xanthines. Merbaphen, the first to be introduced, has been almost completely displaced in recent years by salyrgan, which is regarded as more potent and less toxic. These are organic mercurial compounds containing about 10 per cent of mercury and are effective when administered by intravenous or intramuscular injection or in the form of rectal suppositories. Their effectiveness is greatly increased if acid-producing salts are administered by mouth for several days preceding the injection, and this preliminary medication should be a routine unless the need for the first injection is urgent. Ammonium chloride and ammonium nitrate are the salts most commonly used, but calcium chloride and calcium nitrate are also effective. It has been shown⁸ that there is a true synergism between these salts and the mercurial preparation; all four regularly cause a lowering of the carbon dioxide combining power of the plasma and increase the diuretic response. Alkalinizing salts cause a rise in the carbon dioxide combining power and a decrease in the diuretic effect, while neutral salts cause no change in either function. The statement is often made that doses of these acid-producing salts as large as from 90 to 120 grains (6 to 8 Gm.) a day must be given in order to secure satisfactory results, but my experience is in accord with that of Thomson,⁹ who has found doses of from 60 to 90 grains (4 to 6 Gm.) quite sufficient. Even these smaller doses will almost invariably cause nausea and vomiting unless administered in the form of enteric coated tablets, which are taken by most patients without discomfort in the doses mentioned.

The mercurials for injection are available in ampules containing 1 and 2 cc. It is customary to give only from 0.5 to 0.75 cc. at the first injection, in case there should be an idiosyncrasy to mercury or some untoward reaction, both of which are rare. Subsequent doses are usually 2 cc. If the patient requires a series of injections it is satisfactory to continue ammonium chloride without interruption and inject the mercurial every third, fourth or fifth day. The results are almost always satisfactory and sometimes astonishing; it is not unusual to secure a urinary secretion of from 6 to 10 liters in twenty-four hours, and quantities as large as 15 or 16 liters have been recorded.

A few years ago Shelling and Tarr⁹ reported that the diuretic effect of salyrgan might be increased by combining magnesium sulfate with it. They recommended the use of 15 cc. of 50 per cent magnesium sulfate with 2 cc. of salyrgan and 1.5 cc. of 5 per cent procaine hydrochloride, the whole to be mixed thoroughly in a 20 cc. syringe and injected deeply into the

gluteal muscles. There can be no question that this combination is sometimes remarkably efficacious with patients who have shown little or no response to salyrgan alone. To secure such effects, however, it is not always necessary to use such large quantities of magnesium sulfate; a mixture of 2 cc. of salyrgan, 6 or 8 cc. of 50 per cent magnesium sulfate and 2 cc. of 1 per cent procaine hydrochloride solution has often given excellent results. This is about half the total quantity recommended by Shelling and Tarr, and its injection into the muscles seldom causes pain at the time or later. It should be added that the anterior muscles of the thighs are more suitable for such injections than are the gluteal muscles if the patient is confined to bed.

It is generally agreed that the mercurial diuretics owe their effect largely, if not exclusively, to a direct action on the renal tubules, diminishing their power of reabsorption.

Since there was a widespread belief that the xanthines caused diuresis chiefly by increasing glomerular filtration and the mercurials by diminishing tubular reabsorption, it was but natural that attempts should be made to secure a more effective diuretic agent by combining the two substances. In Europe such a combination was introduced as early as 1929; several years later it appeared in this country under the name mercupurin. According to the revised supplement to New and Non-official Remedies 1939, it contains 10 per cent of the mercurial component and 4.86 per cent of anhydrous theophylline; each cubic centimeter contains about 39 mg. of mercury in nonionizable form. DeGraff and his collaborators¹⁰ in a series of important studies have shown that the addition of theophylline to a mercurial diuretic causes much more rapid absorption from the site of intramuscular injection and also renders it far less injurious to the tissues. Comparative clinical studies have shown that the combination of the two substances is a more potent diuretic than is the mercurial alone, and this increased potency is apparently due entirely to the addition of theophylline. The advantages of combining the two have been so apparent in recent years that practically all mercurials now marketed in Europe have been modified by the addition of 5 per cent theophylline. Several years ago salyrgan was thus modified and is available under the name salyrgan-theophylline; apparently its content of mercury and of theophylline is approximately the same as that of mercupurin. More recently there has been introduced a combination of the two under the name esidrone, which is said to contain 31.2 per cent mercury in nonionizable form and 28 per cent theophylline, which is chemically connected with the mercury molecule. The reports on its clinical use thus far available¹¹

are not sufficient to determine whether the great increase in the amount of theophylline in the mixture has caused any considerable increase in its diuretic potency. [The product has not been accepted by the Council on Pharmacy and Chemistry.—ED.]

There can be no question that the combination of a mercurial with theophylline is the most powerful diuretic agent now available for most patients with congestive heart failure.

Both salyrgan and the mercurial component of mercupurin are available in the form of rectal suppositories, each containing approximately 0.5 Gm. of mercury and a small amount of local anesthetic to prevent rectal irritation. A cleansing enema usually precedes the insertion of the suppository, and the diuretic response is often increased by the preceding administration of the acid-producing salts. Some observers have found the suppositories to be almost as effective as intravenous or intramuscular injections of the mercurials, but most regard them as about one third to one half as effective. (It should be noted that the suppositories of salyrgan have recently been found to result in rectal irritation or ulceration in so many cases that their acceptance has been rescinded by the Council on Pharmacy and Chemistry, and many clinicians have discontinued their use.¹²) Similar unfortunate results have apparently not followed the use of mercurin suppositories, but any such preparation should be used with great caution and should be discontinued immediately on the appearance of signs of local irritation.

There is general agreement that the mercurials should not be used in the presence of acute nephritis or ulcerative colitis. For some years fear was expressed that they might cause serious injury to the renal tubules, and a few such instances have in fact been reported. But the accumulated experience of the past ten years justifies the statement that the mercurial diuretics, especially those combined with theophylline, are safe and highly effective and often retain their full potency after hundreds of injections over a period of many months or years. In the great majority of cases, even of chronic nephritis, there is no evidence that the kidneys have been injured by the mercury.

Potassium Salts.—According to Keith and Binger,¹³ potassium salts were recommended for the treatment of dropsy as early as 1679. In recent years most of the studies relating to their diuretic action have been concerned with nephritic patients, but in 1932 Barker¹⁴ reported excellent results from the administration of potassium chloride to a group of patients whose edema was due to congestive heart failure. He emphasized the importance of placing such patients on a full general diet with an excess of acid ash in which a low ratio of sodium to potassium is maintained. The dose of potassium chloride found to be effective in most of his cases was 5 Gm. (75 grains) a day; this amount was given to the patient each morning in a salt shaker and sprinkled on the food instead of sodium chloride. At the end of the day any salt remaining was dissolved in water and taken by mouth. Twelve of his sixteen patients obtained excellent results, and he observed, as others had done, that no ill effects followed even if very large doses were given for long periods.

In a later and more elaborate study, Keith and Binger¹⁵ found that potassium salts gave "very satisfactory diuretic results" in 48 per cent of their sixty cases and fair results in another 33 per cent, but their figures do not indicate in how many of these edema was due to heart failure. After a careful study of five potassium salts they concluded that the nitrate was preferable, since it frequently caused diuresis and seldom gave rise to untoward effects. They pointed out that any potassium salt must be given in large doses, amounting to 12.5 Gm. or more of the nitrate a day, but state that smaller doses should be administered first. One of their patients took 24.5 Gm. of potassium salts daily for thirteen days and 871 Gm. in sixty-eight days without complaints or toxic symptoms! The salts may be administered in powder form or in solution, but the most satisfactory method is by means of enteric coated tablets containing 7½ grains (0.5 Gm.) each. Like ammonium chloride and ammonium nitrate, the potassium salts may be used in conjunction with other diuretics to enhance the action of the latter.

A great many studies are in complete harmony in indicating that in the experimental animal, in normal human subjects and in patients with edema due to several different causes the replacement of sodium by potassium results in increased excretion of water, while the substitution of sodium for potassium results in increased retention of water. The exact mechanism responsible for these results, however, is not entirely clear. It is known that potassium is quickly absorbed from the intestine and is promptly excreted by the kidney, which is able to concentrate it as much as fifty times; even after large doses the amount in the blood is seldom elevated appreciably and often not at all. In fact the careful measurements of Barker¹⁴ revealed practically no changes in the sodium, potassium, calcium, carbon dioxide combining power, p_{H} , or cholesterol of the blood during the administration of potassium. In some cases it seems possible that the diuresis is linked with a shift in the acid-base equilibrium, but this cannot be demonstrated regularly.

Bismuth.—Ten years ago, Mehrrens and Hanzlik¹⁵ brought forward evidence indicating that certain bismuth preparations injected intramuscularly in small doses act as a diuretic and are almost devoid of toxic manifestations. In the following year Hanzlik and his co-workers¹⁶ cited case reports indicating that bismuth sodium tartrate injected in doses of one half grain (0.03 Gm.) often caused prompt diuresis which was maintained for from four to eighteen days, the average being six days. It was particularly satisfactory in cases of edema due to heart failure, and in the cases cited it was far more effective than merbaphen or theophylline with sodium acetate. Several years later Stockton¹⁷ reported the results of intramuscular injections of bismuth sodium tartrate in thirteen cases of edema in which there had been no response to treatment with digitalis and the xanthine and mercurial diuretics. Congestive heart failure was present in nine of these. Bismuth sodium tartrate caused marked diuresis in ten cases and moderate diuresis in one; four showed no diuretic response either to this or to other agents. The average duration of diuresis after the injection of a bismuth preparation was four days.

17. Stockton, A. B.: Bismuth Diuresis and the Blood and Urinary Changes Under Clinical Conditions, *Arch. Int. Med.* **50**:142 (June) 1932.

These reports are so encouraging that it is surprising not to encounter further reports in recent medical literature. Untoward actions or toxic effects cannot explain this apparent neglect, for these are absent or negligible; in fact, Hanzlik¹⁸ states that the group of observers at Stanford University has used bismuth preparations in various ways in several thousand cases and in animals in the past twelve years without serious disturbances, injuries or fatalities. It seems probable that this drug, like others of undoubted merit, has failed to come into general use because the mercurial diuretics are usually more potent, even though their action is less sustained than that of bismuth.

According to Stockton,¹⁹ bismuth sodium tartrate probably causes diuresis by general tissue action, resulting in mobilization of chlorides and water. He explains the effect of the mercurial diuretics and of theophylline in the same way, whereas most students today believe that these substances act directly on the kidney. A belief in general tissue action of diuretics was widespread ten years ago but has been largely abandoned in the light of recent studies.

Urea.—Although urea has been recommended as a diuretic in renal disease for a long time, its use for the treatment of cardiac edema seems to date from the report of Crawford and McIntosh²⁰ in 1923. They found it to be of great value in seven of eight cases in which edema was due to heart failure and recommended it both for the removal of edema and to prevent its recurrence. No toxic effects were observed. In 1932 Miller and Feldman²¹ emphasized several of the cardinal virtues of this substance, demonstrating that its diuretic potency does not diminish during months or years of practically uninterrupted use, that there are no demonstrable deleterious effects on the kidneys or other tissues and that it acts, alone or in conjunction with other agents, as an admirable prophylactic to prevent the recurrence of edema.

Large doses are required, varying from 15 to 60 Gm. or more (225 to 900 grains) a day. It is administered most satisfactorily in ice cold aqueous solution three times a day immediately after meals. Its unpleasant taste, which is practically its only disadvantage, can be mitigated for some patients by dissolving it in syrups or fruit juices. Syrup of acacia has been especially recommended as a vehicle for urea, its colloidal nature serving to mask the urea quite satisfactorily. Urea is rapidly absorbed from the intestine and is practically devoid of action in the tissues, even in large doses. After it has been taken for a few days the blood nitrogen should be determined to ascertain whether it is being properly excreted. In almost all instances of congestive heart failure, and even of nephritis and nephrosis, it is readily excreted and carries with it large quantities of water. This mechanical diuretic action is thought to be enhanced by decreased reabsorption in the renal tubules.

Urea is an extremely valuable diuretic and deserves wider popularity than it seems to enjoy at present. All available clinical reports emphasize its complete freedom from untoward actions and its extraordinary constancy of diuretic effect. While it is usually less dramatic in its immediate results than are the mercurials, it has obvious advantages and may be used to

supplement the latter. There are but few patients who cannot take it for at least several weeks at a time, and many continue it for months or years without interruption.

NEPHROSIS

Despite the enormous literature devoted to the subject of nephrosis in the past thirty-five years, there is not yet complete agreement among authoritative observers as to the existence of "pure" or "lipoid" nephrosis as a separate disease entity. There is, however, general agreement that the combination of low serum proteins, profuse albuminuria, normal blood nitrogen and edema may properly be known as the "nephrotic syndrome" and that its treatment is the same whether it is regarded as resulting from a specific renal lesion, a nonspecific renal lesion (one stage in the development of chronic glomerulonephritis) or a general metabolic disease. The edema is thought to be due in large measure, as Epstein²² first pointed out, to the marked hypoproteinemia, which results in great lowering of the colloid osmotic pressure of the blood.

The general principles of treatment include maintenance of the nutrition at the highest possible level by an adequate diet high in protein, limitation of salt and fluid intake and exercise in moderation as long as the clinical state permits. Practically all known diuretics have been tried in this condition; any of them may give satisfactory results in a given case but most of them prove quite ineffective. Thyroid has been extensively used because of the low basal rate in most patients but is seldom effective in causing diuresis, possibly because the low metabolic rate is caused in most instances by the undernutrition rather than by thyroid deficiency. The xanthine diuretics have proved useless in the hands of most observers. Encouraging results have sometimes been obtained from the use of potassium salts, as already outlined. Urea also has occasionally been effective in doses of from 15 to 50 Gm. or more a day and deserves a trial if it is tolerated. But there can be little question that the mercurial diuretics are much the most effective in the majority of cases, and they may be used without fear of increasing the renal lesion. They should be preceded by one of the acid-producing salts. In many cases the mercurials also are useless.

Because of the belief that the edema is due largely or wholly to the reduction of serum proteins, many attempts have been made to raise these to normal levels by means of diets high in protein and by the intravenous injection of such substances as whole blood, blood plasma and solutions of acacia. Leiter²³ has stated that this form of treatment, however plausible it may seem, is inevitably doomed to failure because the amount of material injected cannot be sufficient to cause an appreciable increase in the colloid osmotic pressure of the plasma and because it will be rapidly excreted from the circulation, since the glomeruli are much more permeable to colloids than normally. However, Hartmann and his collaborators,²⁴ Lepore,²⁵ Landis²⁶ and Shelburne²⁷ have all reported excellent results from the repeated and cautious intravenous injection of acacia solutions. The strength of the solutions has usually

been from 6 to 15 per cent, in water or in physiologic solution of sodium chloride, and the injections may be given daily or at intervals of from two to four days. In practically all reported cases of benefit from acacia many diuretics had been tried without success. Following the disappearance of edema, a diet high in protein should be continued; Shelburne regards this as an essential part of the treatment.

The administration of acacia is not wholly without disadvantages, and some²⁸ have stated that these are so serious as to make the use of the substance unjustified. The work of Dick²⁸ is often quoted in support of this belief, but Shelburne²⁷ has recently pointed out that this work is open to serious criticism and should not prevent the proper use of a valuable therapeutic agent. Immediate reactions to injections of acacia are infrequent if the solutions are freshly and carefully prepared, but serious reactions have followed the use of impure solutions. It seems clear that if acacia is to be used it should be in a hospital rather than in the patient's home. If other methods of treatment have been tried without success and the removal of edema is highly desirable, recent experience would certainly justify the trial of acacia. If this also proves ineffective, other diuretics should be employed immediately after the acacia, as they may then prove beneficial.²⁹

VITAMIN DEFICIENCY

In the past several years evidence has been presented, chiefly by Weiss and his collaborators,²⁹ indicating that deficiency of vitamins, especially of vitamin B₁, may lead to various types of cardiovascular dysfunction, whether the heart was previously normal or diseased. The cardiovascular manifestations do not form a fixed clinical syndrome but may include the characteristic signs of congestive heart failure with marked edema. The diagnosis of the condition may be very difficult, but the possibility of vitamin deficiency should be seriously considered when any patient with an abnormal nutritional history develops the syndrome of heart failure with edema in the absence of convincing signs of heart disease. The presence of other signs of vitamin B₁ deficiency, especially polyneuritis, glossitis and cutaneous changes suggestive of pellagra, may give an important clue. According to Strauss³⁰ "it is rare to observe 'beriberi heart' without at least minimal signs of polyneuritis." Both Weiss and Strauss emphasize the possible importance of measurements of the circulatory velocity and the minute volume output of the heart, as these are increased in the condition now under discussion and are conspicuously slowed in heart failure due to other causes. The response to specific therapy, however, may provide the first and most convincing evidence of the nature of the condition.

General, or nonspecific, treatment consists of the application of the measures enumerated previously: rest in bed, limitation of fluids and of salt and the administration of digitalis and diuretics. Some patients respond well to such a regimen, while others show little or no improvement; indeed, some of Weiss's patients became worse when placed at rest. Specific treatment consists of the administration of vitamin B₁. Preferably this should begin with the intravenous or intramuscular

injection of from 20 to 50 mg. of thiamin chloride N. N. R. daily, and this method should be employed as a routine in the more severe cases. After improvement has occurred, usually within two weeks, the dose may be decreased to 10 or 20 mg. daily, or the larger doses may be given by mouth. If the symptoms are not particularly severe or have been largely relieved by intensive treatment, brewers' yeast may be used instead of the crystalline form of the vitamin; doses of about 30 Gm. three times a day are recommended.

The response to such treatment may be prompt and spectacular, with marked improvement in a few days and complete disappearance of symptoms and signs within two or three weeks, or improvement may be gradual over a period of six or more weeks. Rapid improvement is said to be associated with diuresis, slowing of the heart rate and rise in the arterial pressure. If there is not clear evidence of improvement after adequate dosage of vitamin B₁ for several weeks it is probable that the cardiovascular manifestations are not due to vitamin deficiency. Beneficial effects do not follow the administration of this vitamin to patients with other types of heart failure.

Weiss has properly emphasized that deficiencies are seldom limited to a single vitamin, and these patients often present evidences of inadequate intake of vitamin A and of ascorbic (cevitamic) acid, of anemia, of hypoproteinemia and possibly of other dietary deficiencies. These should, of course, receive appropriate treatment simultaneously.

MALNUTRITION

The edema, often very extensive, associated with serious degrees of malnutrition is thought to be dependent in large part on the diminished proteins of the blood plasma and the consequent lowering of the colloid osmotic pressure. It is clear that this condition may be intimately related to and complicated by the vitamin deficiency state just discussed. Diuretics may be employed, but the logical and highly effective treatment is the correction of the nutritional state by means of a proper diet rich in proteins and in vitamins. Unless the patient is dying, the dropsy usually disappears with gratifying promptness.

PICK'S DISEASE

For many years the term "Pick's disease" was used loosely and inaccurately and was applied to a number of quite different pathologic states. Now, thanks largely to the clinical reports of White³¹ and the experimental and surgical studies of Beck,³² it is possible to say with conviction that Pick's disease is actually chronic constrictive pericarditis. For the details of this important advance in our knowledge, their original papers and those of Churchill³³ and of Burwell³⁴ should be consulted. Among the more important clinical features of the condition may be mentioned gradual onset of dropsy, disproportionate enlargement of the liver and ascites, increased venous pressure, low arterial pressure and a heart that is normal in size or smaller than normal. A single cause is responsible for all these manifestations: the heart is so encased by unyielding fibrous

or calcified tissue as to be unable to dilate and fill properly during diastole. In some cases there is, in addition, marked constriction of the inferior vena cava. The immediate mechanisms of edema formation are those discussed under congestive heart failure.

The milder diuretics are of little or no value in this condition, although they may occasionally lengthen the interval between abdominal paracenteses. The mercurials, however, may prove extremely useful, as in the case reported by Noth.³⁵ A man aged 53 in seven and one-half years had had forty abdominal paracenteses and 450 injections of mercurial diuretics and had taken 6 Gm. (90 grains) of ammonium nitrate a day for three years. At the end of this time he presented no signs of hepatic or renal injury and had been able to continue an active life as a banker. However, if the diagnosis is reasonably certain and the patient is a good operative risk, the best treatment is surgical resection of the constricting pericardium. This often results in rapid and spectacular improvement and in restoration of the patient to normal activity, even after years of invalidism.

NEPHRITIS

The edema of acute nephritis is generally believed to be due in large part to widespread injury to the capillaries, which makes them more permeable than normally. It is theoretically unwise to administer diuretic drugs which might irritate an organ already acutely inflamed, and experience has shown conclusively that they are practically always devoid of beneficial action. In most cases diuretics are clearly unnecessary; if special circumstances seem to make a trial of such drugs essential, only the very mildest, such as urea or theobromine with sodium salicylate, should be used.

In chronic nephritis also diuretics are usually unnecessary if one excludes the "nephrotic syndrome" of chronic glomerulonephritis. But if edema becomes a serious problem almost any of the diuretics previously discussed may be used safely. The xanthines, urea and potassium salts may prove ineffective. The mercurial diuretics, combined with ammonium chloride or nitrate, are usually very satisfactory and almost never increase the renal disease. It is unwise to use these if there is acute renal inflammation or much retention of nitrogen in the blood, but extensive edema and nitrogen retention are seldom associated.

HEPATIC CIRRHOSIS

It is not often that ascites and edema of the lower extremities resulting from portal cirrhosis of the liver can be removed satisfactorily by means of diuretic drugs. It has been the almost universal experience that the milder ones, including the xanthines, urea and bis-muth, are almost devoid of beneficial action. In occasional cases the mercurials, preceded by acid-forming salts, prove to be fairly satisfactory, but in most instances all that can be expected is a prolongation of the interval between abdominal paracenteses. This, however, is distinctly worth achieving, and a trial is always justified.

COMMENT

Even from the foregoing survey it is clear that the occurrence and removal of dropsy may present involved and baffling problems to the physician. Proper treatment of the underlying disease may result in disappearance of the edema, but often this must be supplemented by control of the diet, by diuretics and in some cases by surgical operation. It is highly encouraging to realize

that all the specific measures discussed in this article, with the exception of the xanthines, have come into general use in this country within the past fifteen years. Our knowledge of the mechanisms involved in the formation of edema and the occurrence of diuresis have steadily widened, and our use of specific remedies has consequently become more intelligent. It is not often that the disease responsible for dropsy can be wholly cured, as in vitamin deficiency and constrictive pericarditis, but the dropsy itself can often be controlled very satisfactorily by means of medical treatment for many months or years.

303 Whitney Avenue.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

CARRIER ROOM VENTILATOR, TYPE 56B, ACCEPTABLE

Manufacturer: The Carrier Corporation, Syracuse, N. Y.

The Carrier Room Ventilator, Type 56B, is designed to cause the circulation of outside and inside air in a room and to filter out dust and pollen. The unit is equipped with a fluted filter consisting of two layers of erinoline enclosing a thin layer of cotton and fastened in a sturdy cardboard case. The unit also contains two motor-driven sirocco type blowers mounted in a metal case with louvers for the air outlets. The intake is located in the lower back of the unit, where it extends out of the window. A damper provides means for adjusting the proportions of outside and recirculated air. Sound insulation is also provided in the mechanism.

The ventilator comes in two sizes, the smaller one providing 250 cubic feet of air per minute and designed for average sized rooms. Dimensions are 24 inches long by 11½ inches deep and 9 inches high; the shipping weight is approximately 35 pounds. The larger size, designed for larger rooms, offices and apartments, supplies up to 500 cubic feet of air per minute. Dimensions are 31 inches long, 11½ inches high and 14¾ inches deep; the shipping weight is approximately 50 pounds.

The standard fan motor is a 110 volt, 60 cycle, single phase type. The larger unit has a variable speed adjustment; the smaller unit a single speed motor. The filter fits in the frame attached to the hinged top cover of the unit and is held in place by two adjustable levers.

The firm claims that the unit "supplies cleaned, outside air, without drafts; circulates filtered, refreshing, room air; shuts out noise, dirt, dust and pollen." The firm submitted evidence to support these claims and the following Council investigation was also conducted to test their validity:

The unit was installed as it would be in practice, and tests were conducted during a portion of the 1939 ragweed, hay fever season. Greased slides were placed at the outlet louvers, examined for pollen and compared with slides exposed outdoors. These tests showed an efficiency of the unit for pollen removal of more than 97 per cent for the first week of operation. It was permitted to run continuously for another week and again tested. There was no change in filters, the filters having been used for two weeks of continuous operation. At the end of this time the efficiency had dropped to 96 per cent for pollen removal. Apparently the filter loses some of its efficiency in time for holding pollen. The filter is of the discardable type and should be renewed as frequently as local conditions demand. The tests were conducted when there were large quantities of dust in the air. Coarse particles of dust may, by repeated bombardment

Carrier Room Ventilator,
Type 56B.

35. Noth, P. H.: Pick's Disease: A Record of Eight Years' Treatment with Salrgan, Ammonium Nitrate and Abdominal Paracentesis. Proc. Staff Meet., Mayo Clin. 12: 513 (Aug. 18) 1937.

against the filter; rupture it sufficiently to allow passage of pollen, but this may happen to any filter.

In view of the foregoing report the Council on Physical Therapy voted to accept the Carrier Room Ventilator, Type 56B, for inclusion on the Council's list of accepted devices.

COLD QUARTZ ULTRAVIOLET LAMP EXEMPLAR MODEL ACCEPTABLE

Manufacturer: E. J. Rose Manufacturing Company, 727-733 East Gage Avenue, Los Angeles.

The Cold Quartz Ultraviolet Lamp, Exemplar Model, catalogue number 4005, provides ultraviolet generators of the body grid, tangency equalization and orificial types, and is designed strictly for use by physicians. The main lamp assembly consists of a detachable fused quartz grid attached to a corrugated aluminum reflector mounted to a reflector case; the dome shaped reflector case has an outside diameter of 31 cm. (12 $\frac{1}{4}$ inches) and consists of a bakelite back covering the burner electrodes and an aluminum shell which acts as a support for the burner and its reflector. The lamp is attached to a horizontal arm which pivots both at the upright standard and at a section joint. The arm may thus be extended to the full length of 25 inches or folded to a smaller length. The transformer, automatic timer, connecting receptacle for body grid and orificial generators and line cord connection are mounted in the floor base, while the orificial generator is contained within a case on the vertical part of the stand.

Fig. 1. Spectral energy distribution of the Cold Quartz Ultraviolet Lamp, Exemplar Model.

The lamp may be adjusted up to a height of 60 inches, and a pneumatic cushion is provided to prevent accidental shock to the grid element while it is being lowered. The lamp may be furnished either with the body grid generator alone (number 4005-B) or with the body grid plus the orificial generator, orificial cable, rayon protective sleeving and two pairs of goggles (number 4005-C).

Tubing of the grid is coiled in a flat, hexagonal pattern, is 7 mm. in diameter and has an exposed length of 60 inches. It is highly evacuated of air and the space is supplanted with an atmosphere of rare gases, xenon, krypton and argon, and a few drops of mercury. The cold quartz orificial unit is made of double core, fused quartz tubing and has a bakelite handle or case covering the electrode terminals. A high tension cable connects this unit to the standard high voltage transformer at the top of the tubular column.

The firm provided physical data from a reliable laboratory abstracted as follows: The power consumption of the lamp is 62 watts at 115 volts. During a two hour continuous test, no part of the lamp or transformer became heated. It produced 900 microwatts per square centimeter of ultraviolet radiation at 16 inches. The spectral energy distribution measured by an ultraviolet photometer was 89 per cent between 2,000 and 2,600 angstroms, 10 per cent between 2,600 and 3,000 angstroms and 1 per cent between 3,000 and 3,200 angstroms. A spectrogram is shown in figure 1.

The orificial unit had the same spectral distribution as the general body lamp and sufficient energy to develop a perceptible erythema in less than one second when applied directly to the untanned skin. Physiologic tests on abdominal untanned skin

confirmed the photometer measurements as to erythema time with the body lamp. Physiologic tests gave a perceptible erythema in thirty seconds at 16 inches.

Tests made for the Council substantially confirmed this report. The Council on Physical Therapy voted to accept the Cold Quartz Ultraviolet Lamp, Exemplar Model, for inclusion on the Council's list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

E. R. SQUIBB & SONS WAS NOTIFIED OF THE ACCEPTANCE OF AMNIOTIN IN MAY 1939. AT THE TIME THAT THE DESCRIPTION WAS READY TO APPEAR IN THE JOURNAL, THERE AROSE QUESTIONS CONCERNING FURTHER CONSIDERATION OF THE STANDARDS. IT SEEMED ADVISABLE, THEREFORE, TO DEFER PUBLICATION OF THE ACCEPTANCE IN ORDER THAT, AT THE SAME TIME, THE REVISED STANDARDS MIGHT BE INCLUDED.

PAUL NICHOLAS LEECH, Secretary.

AMNIOTIN.—A liquid containing a highly concentrated, noncrystalline preparation of estrone (ketohydroxyestrin) together with a small varying amount of other estrogenic ketones extracted from the urine of pregnant mares.

Actions and Uses.—Amniotin is used either orally or by hypodermic injection of an oil solution in the same conditions for which estrone (theelin) and estriol (theelol) are recommended.

Dosage.—From 2,000 to 20,000 international units injected one or more times weekly depending on the response of the patient. After relief has been produced, dosage may be lowered to a maintenance level. As much as 15,000 international units per week may be required in resistant cases of kraurosis vulvae. Amniotin suppositories are valuable adjuncts in the treatment of senile vaginitis.

Occasionally a considerable amount of uterine bleeding occurs in menopausal women following large doses of estrogenic substance. This may be quite alarming at times and it is therefore suggested that the dose be reduced as soon as feasible.

For gonorrheal vaginitis in children from 1,000 to 2,000 international units daily in glycerogelatin suppositories may be required. This may be supplemented by intramuscular injection of small doses of the oil solution, if necessary. Changes in the secondary sex organs may be produced by this therapy, particularly if it is too prolonged. These changes usually regress on cessation of treatment. Estrogenic products must be used with care.

Amniotin capsules, 1,000 or 2,000 international units, one or more times daily may be administered orally alone or as a supplement to parenteral therapy.

Urine from pregnant mares, collected after the fifth month of pregnancy, is acidified with hydrochloric acid to pH 1.5 and boiled for three hours. The hydrolyzed urine is extracted with ethylene dichloride, and the extract evaporated to dryness. The residue is dissolved in ether, the ether solution is washed with half saturated sodium carbonate solution, followed by tenth normal sodium hydroxide and finally the ether removed by distillation. This residue is dissolved in normal sodium hydroxide, amniotin is extracted from the toluene with normal sodium hydroxide. This alkaline extract, after neutralization with hydrochloric acid, is extracted with toluene, and the toluene solution, after washing with water, is evaporated to dryness.

This residue is further purified by high vacuum fractional distillation. The resulting residue is dissolved in sterile vegetable oil for hypodermic and oral use and incorporated in a glycerin gelatin base for vaginal administration.

Amniotin is assayed by a modification of the Conard and Burn method in direct comparison with the international standard. The international unit is defined by the League of Nations Health Organization as the specific estrus producing activity contained in 0.1 microgram (0.0001 mg.) of the standard crystalline ketohydroxy estrin ($C_{18}H_{26}O_2$). The physiologic criterion of activity is the appearance of cornified cells in the vaginal smear of a castrated rat.

Manufactured by E. R. Squibb & Sons, New York, N. Y. No U. S. patent. Trademark No. 318536.

Amniotin in Oil, 2,000 International Units: Each cubic centimeter contains 2,000 international units of estrogenic substance.

Amniotin in Oil, 10,000 International Units: Each cubic centimeter contains 10,000 international units of estrogenic substance.

Amniotin in Oil, 20,000 International Units: Each cubic centimeter contains 20,000 international units of estrogenic substance.

Amniotin Capsules, 1,000 International Units: Each capsule contains 1,000 international units of estrogenic substance.

Amniotin Capsules, 2,000 International Units: Each capsule contains 2,000 international units of estrogenic substance.

Amniotin Capsules, 4,000 International Units: Each capsule contains 4,000 international units of estrogenic substance.

Amniotin Pessaries, 1,000 International Units: Each pessary contains 1,000 international units of estrogenic substance in a glycerogelatin base.

Amniotin Pessaries, 2,000 International Units: Each pessary contains 2,000 international units of estrogenic substance in a glycerogelatin base.

In 1935 the Council on Medical Education and Hospitals published a report of a two year study of tuberculosis facilities in the United States.¹ This was based on the inspection of 656 hospitals and sanatoriums, the analysis of 602 special questionnaires, and supplementary reports from 5,600 other hospitals that had been requested to furnish information concerning the hospitalization of tuberculous patients.

The original report contained the names of 1,240 institutions, 471 sanatoriums, 740 tuberculosis departments and twenty-nine preventoriums, all listed in accordance with the following classification: 1. Sanatorium—an institution operating exclusively for the treatment of tuberculosis. 2. Tuberculosis department—a hospital service devoted in part to tuberculosis care. 3. Preventorium—a separate unit for tuberculous contacts or children with the first infection type of disease. The preventorium classification did not include summer camps for children or preventorium units conducted as part of a sanatorium or other hospital service.

The same terminology will be retained in the present report, although additional information is now available concerning preventorium facilities in the sanatorium group.

PURPOSE OF SURVEY

The present report constitutes a follow-up on the survey of 1933-1935, conducted in large part by Fritjof H. Arestad, M.D., of the Council's staff of hospital examiners, who also directed the former study. It serves mainly to indicate the current status of tuberculosis hospitalization by recording changes in bed capacity and patient population over a period of five years, but also has for its purpose the presentation of factual data that can be utilized as a quantitative measure in the evaluation of sanatorium facilities.

A qualitative analysis is not a primary consideration at this time yet the report cannot help but reflect the degree of standardization that has been attained in individual institutions. Thus the survey should prove useful in the interpretation of sanatorium needs, a function that can best be ascribed to physicians specializing in tuberculosis, directors of sanatorium services, departments of health, tuberculosis associations and other agencies intimately concerned with the problem of tuberculosis control.

METHOD OF STUDY

The information required in the present investigation of sanatorium facilities was readily obtained in connection with the Annual Census of hospitals registered

(II) Tuberculosis Service:

(A reply is desired from all tuberculosis sanatoriums, hospitals and departments which admitted tuberculous patients during the twelve month period listed above.)

1. Number of beds set aside for tuberculosis:
For adults..... For children..... Total.....
2. How many of children's beds are for preventorium care?.....
3. Patients admitted to tuberculosis service during year:
Men..... Women..... Total.....
Children (under 15 years).....
4. Of patients admitted how many were received by transfer from other tuberculosis institutions?.....
Minimal pulmonary tuberculosis..... Moderately advanced..... Far advanced.....
Nonpulmonary tuberculosis..... Other.....
5. Condition on admission: Number of first infection type.....
6. Tuberculous patients discharged during year (exclude deaths):
Men..... Women..... Total.....
Children.....
7. Of patients discharged how many were transferred to other institutions?.....
8. Number of deaths from tuberculosis.....
9. Census of patients in tuberculosis division:
a. At beginning of twelve month period:
Men..... Women..... Children Under 15..... Total.....
b. Average daily census during year:
Men..... Women..... Children Under 15..... Total.....
c. Census on Sept. 30, 1938:
Men..... Women..... Children Under 15..... Total.....
10. Number on waiting list Sept. 30, 1938.....
11. Is pneumothorax available for inpatients?.....
For outpatients?.....

1. Survey of Tuberculosis Hospitals and Sanatoriums in the United States. J. A. M. A. 105:1855 (Dec. 7) 1935.

by the American Medical Association. Accordingly, it did not seem necessary to repeat the inspection procedure carried out in the previous survey.

After consultation with the National Tuberculosis Association, the questionnaire on the preceding page was incorporated in the regular information blanks forwarded to 6,198 hospitals during the latter part of 1938.

Other sections of the blank requested information concerning ownership and control, scope of hospital and outpatient service, x-ray and laboratory facilities, nursing personnel, interns, resident physicians and medical staff.

patients admitted or treated during the year. This group includes 479 sanatoriums, 630 tuberculosis departments and thirty-one preventoriums. In addition there are 584 hospitals that admit tuberculous patients or conduct tuberculosis clinics yet did not report the extent of their service.

The variation from the 1935 report showing 1,240 institutions is largely a decrease in the number of tuberculosis departments from 740 to 630. This, in turn, is mainly a reduction in the nervous and mental field, in which only ninety-two departments were reported as compared to 193 in the previous survey.

Reports were received from 5,950 hospitals, including all of the sanatoriums, the principal tuberculosis departments and all hospitals approved for intern and residency training. The completeness of returns, as measured by a total response of 96 per cent (99 per cent of bed capacity), testifies to the splendid cooperation extended by hospital and sanatorium superintendents. The statistical data included in this report represent a twelve months period ended either Sept. 30 or Dec. 31, 1938.

NUMBER OF TUBERCULOSIS INSTITUTIONS

Listed in the present report are 1,140 institutions that have either specified the number of beds for tuberculosis or else indicated the number of tuberculous

The sanatoriums in operation at the present time include nineteen federal, seventy-two state, 182 county, twenty municipal, sixteen city-county and 170 under private control. Reference should be made to table 1 and also to the corresponding section of the 1935 report. Of the federal sanatoriums, six are operated by the United States Veterans Bureau, one by the United States Public Health Service and twelve by the Indian Administration of the Department of the Interior.

Table 2, showing classification of tuberculosis institutions by control, contains comparative data for 1934. Included at present are 129 federal departments, 126 state, sixty-two county, sixty-two city, seven city-county and 244 private hospitals. A similar classification of

tuberculosis departments by type and control, as represented in table 3, shows that 439 are in general hospitals, ninety-two in mental institutions, twenty-six in isolation hospitals, eight in orthopedic units and sixty-

administrators. In the tuberculosis departments the corresponding figures are 344, 121 and 165; in the preventoriums, twelve, thirteen and six. Reference should be made to table 4 showing the classification of superintendents in accordance with the type of administrative control.

further description of preventorium facilities in sanatoriums and other hospitals. Included in the preventorium group are seven under county control, two city-county, twenty-one private and one operated by the Indian Administration.

It may be of interest at this time to note that 314 sanatoriums have physicians in charge, eighty-six have nurse superintendents and seventy-nine have lay

admitted or treated during the year. The decrease of ninety-three in this column approximates the reduction of 101 departments in the nervous and mental group as already referred to.

In the general hospitals there are 309 departments of less than twenty-five beds, fifty-one with a capacity of twenty-five to forty-nine beds, thirty-eight of fifty to ninety-nine beds and forty-one in the classification of

100 beds or over. As a rule, the smaller departments are utilized mainly for temporary care — emergency treatments, diagnostic procedures or tuberculosis sur-

gery—while the larger units may well be considered as regular sanatorium services.

Over half of the tuberculosis departments in isolation hospitals have more than fifty beds, yet from the stand-

BED CAPACITY

The survey of 1935 reported 95,198 beds for the treatment of tuberculosis. As indicated in table 7 there are now 98,801 beds available, including 87,084 for adults and 11,717 for children. Incidentally the capacity for children is practically identical with the figure of 11,647 reported in the previous survey. The sanatoriums have 70,713 beds, the tuberculosis departments 25,944 and the preventoriums 2,144. The private group reports 16,946 beds, federal hospitals 9,076 and the remaining public institutions 72,799: state 28,699, county 26,840, municipal 13,759, city-county 3,481. In federal hospitals the bed capacity for tuberculosis showed a decrease of 1,864; in the private group the reduction was 776. The other institutions, however, showed an increase of 6,187.

The federal hospitals report tuberculosis beds as follows: U. S. Army 617, U. S. Navy 152, U. S. Pub-

point of bed capacity alone it would appear that the sanatorium service is the smaller of the two units in most of these institutions. In the sanatorium group thirty-eight have less than twenty-five beds, eighty-six have from twenty-five to forty-nine beds, 141 have from fifty to ninety-nine beds and 214 report 100 beds or more.

Indian Health Service 811, U. S. Veterans Bureau 5,671, Indian Administration 1,609, others 216.

The sanatorium division has 70,713 beds as compared to 64,997 in 1935. The federal sanatoriums have 3,970 beds, state sanatoriums 21,066, county 22,206, municipal 8,486, city-county 2,191, and the private sanatoriums 12,794. Six sanatoriums operated by the

United States Veterans Bureau have 2,713 beds, one under the control of the United States Public Health Service has 244, and twelve assigned to the Indian Administration report 1,013. Included in the sanatorium group are 8,285 beds for children distributed in the following manner as indicated in table 8: Indian Administration 319, state 2,877, county 2,706, city 1,149, city-county 436 and private 798.

Information concerning bed capacity in tuberculosis departments is contained in tables 7, 8 and 9. These indicate that general hospitals have 14,824 beds for tuberculosis, mental institutions 7,189, isolation hospitals 2,813, orthopedic units 283 and other institutions 835, a total of 25,944. This represents a reduction of 2,590 beds since the previous report, although increases of 358 and 257 occurred in the general and isolation hospitals respectively.

show that there were 122,342 admissions in 1938, including 59,599 men, 40,894 women, 13,400 children and 8,449 not classified. The number of readmissions are not known, but patients received by transfer from other institutions totaled 7,254.

The sanatoriums admitted 76,808 patients: 34,308 men, 29,049 women, 8,332 children and 5,119 unclassified. In table 11, showing admissions in tuberculosis institutions according to control, it can be seen that the private sanatoriums admitted 14,644, the federal sanatoriums 5,722 and the remaining public sanatoriums 56,442.

The tuberculosis departments reported 42,230 admissions: 9,178 in federal institutions, 6,880 in private hospitals and 26,172 in the other departments. Admissions to tuberculosis units in general hospitals totaled 34,739, isolation hospitals 4,112, mental institutions

Totals.....	4,768	258	5,026	7,416	137	7,553	3,770	374	4,144	5,114	159	5,273	1,025	135	1,160	2,483	225	2,708	24,656	1,288	25,944

Federal departments reported 5,026 beds, state 7,633, county 4,144, city 5,273, city-county 1,160 and private departments 2,708. Included in these figures are 1,288 beds for children.

In the preventorium group are included thirty-one institutions with a capacity of 2,144 beds. A preventorium operated by the Indian Administration has eighty beds, seven under county control have 490, two classified as city-county accommodate 130 and twenty-one private preventoriums accommodate 1,444.

The preventorium service is more extensive, however, than has been indicated. Tables 27 and 28 show that there are 2,686 additional beds for preventorium purposes: 2,447 in the sanatorium division and 239 in the tuberculosis departments. Thus it is apparent that, of a total of 11,717 beds for children, 4,830 are now utilized for preventorium care.

NUMBER OF PATIENTS ADMITTED

In the previous investigation of tuberculosis facilities it was found that 121,706 patients were admitted during a period of one year. Reference to table 10 will

1,874, orthopedic units 475 and other departments 1,030. This indicates a decrease of 551 patients in the nervous and mental hospitals, 344 in the tuberculosis-isolation group and 2,385 in departments of general hospitals. Tuberculosis departments admitted 1,764 children.

In the preventorium group there were 3,304 children admitted: 100 in a federal preventorium for Indians, 413 in seven county preventoriums, 165 in two operated jointly under city and county control, and 2,626 in twenty-one private institutions. The total of 13,400 children admitted in all the tuberculosis institutions represents a decrease of 2,123 since the last report. Tables 27 and 28 contain further information relative to the hospitalization of children.

PATIENTS DISCHARGED

As shown in table 12, the sanatorium and tuberculosis departments discharged 85,620 patients in 1938, transferred 9,361 and reported 22,081 deaths, a total of 117,062 exclusive of discharges in the regular preven-

toriums. The latter did not list discharges but reported 3,304 admissions, which usually approximate the number of patients released. On the assumption, therefore, that the preventoriums discharged 3,304 patients, it is estimated that deaths, transfers and other discharges in tuberculosis institutions reached a total of 120,366.

This sum is quite similar to the annual admission rate of 122,342.

The sanatoriums discharged 57,952, transferred 3,314 and listed 12,375 deaths. In the departments, however, the number of transfers was 6,047, discharges 27,668 and deaths 9,706.

In 1934 there were 16,229 deaths in the sanatoriums and tuberculosis departments as compared to the present report of 22,081. The greater number of institutional deaths at present may be indicative of a growing use of sanatorium facilities for the care of far advanced, terminal cases.

NUMBER OF PATIENTS TREATED

As a further illustration of the scope of tuberculosis hospitalization, tables 13 and 14 have been prepared to show the number and classification of patients treated

ing to control. It is of further interest to note that 46,036 patients were treated in tuberculosis departments of general hospitals, 6,458 in mental institutions, 6,504 in tuberculosis-isolation hospitals, 481 in orthopedic units and 1,987 in other departments, a total of 61,466.

Data concerning the preventorium division are not complete. However, the reports at hand show 3,322 children treated in the private preventoriums, 469 in the county group, 240 in the city-county division and 163 in the preventorium operated by the Indian Administration, 4,194 in all.

* Admissions in lieu of discharges.

during a twelve months period. The impressive total of 202,021 treated in 1938 agrees closely with the estimate of 203,436 obtained in the previous survey, when 82 per cent of the institutions reported 166,818 patients treated.

The sanatoriums now show a total of 136,361 patients treated, the departments 61,466 and the preventoriums 4,194. In this group are 96,924 men, 69,840 women, 21,324 children and 13,933 unclassified. The private institutions treated 36,211, the federal hospitals 22,046 and the remaining tax-supported institutions 143,764. Reference should be made to table 14 for information concerning the number of patients treated in the various institutions, all of which have been classified accord-

DAILY CENSUS

In the 1935 report it was shown that 81,652 patients were under treatment in tuberculosis institutions on the day of reporting and that the average daily census was 81,952 on the basis of 69,024 patients in institutions, representing 83.8 per cent of the total bed capacity. The present report shows 79,679 patients present at the beginning of the year, 79,300 as the average daily census and 80,403 under treatment at the end of the twelve months period.

Table 15 indicates an average daily census of 61,288 in the sanatorium group, 17,122 in the tuberculosis departments and 890 in the preventoriums. Federal institutions reported an average daily census of 6,766,

state 22,501, county 22,342, city 12,337, city-county 3,065 and private institutions 12,289. For corresponding data concerning the sanatoriums, tuberculosis departments and preventoriums, reference should be made to table 16.

In the group of tuberculosis departments the general hospitals reported an average census of 10,119, mental institutions 3,858, tuberculosis-isolation hospitals

2,448, orthopedic units 207 and other hospitals 490 (table 17). The number of patients present in the sanatoriums, tuberculosis departments and preventoriums at the beginning of the year is shown in table 18.

AVERAGE LENGTH OF STAY

Information concerning the average length of stay was furnished by 456 sanatoriums which reported

22,370,120 treatment days and a total of 136,361 patients treated. Hence the average number of days per patient is 164 as compared to 166 in the previous report. Three hundred and ten tuberculosis departments gave 6,249,530 treatment days to 61,466 patients. This indicates an average stay of 101 days, the identical figure reported in 1935.

Incomplete reports from the preventoriums would indicate an average length of stay of seventy-seven days on the basis of 4,194 patients treated and 324,850 treat-

responsibility in the rehabilitation of patients. Then the period of hospitalization will no doubt be extended to include suitable programs of graduated exercise and courses of vocational training now lacking in most of the institutions. A well balanced sanatorium service is one that gives due consideration not only to prevention and therapy but also to rehabilitative measures that may prevent a further reactivation of the disease. As the incidence of tuberculosis decreases it is logical to assume that further emphasis will be placed on the

Totals.....	24,209	21,658	5,382	10,039	61,288	8,481	4,311	566	3,764	79,300

ment days. The returns were likewise incomplete in 1935, when estimates ranging from seventy-nine to eighty-four days were made.

Tables 19 and 20 refer to the average stay in sanatoriums classified by states and according to control. In the federal sanatoriums the average is 138 days, in state sanatoriums 170, county 171, municipal 175, city-county 156 and private 147. The corresponding figures for 1934 were 172, 166, 173, 170, 165 and 151 respectively.

The average length of stay in the sanatorium group is apparently decreasing as a result of continuing improvements in the medical and surgical therapy of tuberculosis. It may eventually increase, however, when the sanatoriums begin to realize their full

continued hospitalization of far advanced cases especially in states in which there may be an adequate number of tuberculosis beds. This method of protective isolation should also tend to increase the average length of hospitalization.

THE WAITING LIST

The sanatoriums reported 7,572 patients on the waiting list, the tuberculosis departments 1,225, a total of 8,797 as compared to 9,854 in 1935. There were 198 tuberculous patients awaiting admission to Veterans' hospitals, 180 to hospitals of the Indian Administration, 900 to private institutions and 7,519 to the remaining tax-supported institutions: state 5,106, county 1,368, city-county 329 and municipal 716.

Tuberculosis departments in general hospitals reported 888 patients awaiting admission, tuberculosis-isolation hospitals 313 and other departments twenty-four, a total of 1,225.

It is apparent that the present waiting list is largely the result of unequal distribution, since the number of vacant beds, 16,254 in all, exceeds the number of applications now pending by 7,457. As shown in table 21, there are 9,577 vacancies in the sanatoriums, 2,005 more than the number of patients awaiting hospitalization in this group. In the state and city-county sanatoriums, however, the waiting list is considerably greater than the number of vacancies. Vacant beds in the tuberculosis departments total 6,677, or 5,452 more than the number of patients now applying for admission. It should be noted, however, that the municipal departments have a waiting list nearly twice the number of vacancies.

CONDITION OF PATIENTS ON ADMISSION

In the present survey 427 sanatoriums and 345 tuberculosis departments reported on the condition of patients on admission. As shown in table 22, there

Pulmonary cases of the reinfection type totaled 80,088. Of these 12.9 per cent were admitted in the minimal stage, 32.1 per cent as moderately advanced and 55 per cent as far advanced. The report of 1935 showed corresponding ratios of 13.1, 29.7 and 57.2 per cent and the National Tuberculosis Association reported 16, 30 and 54 per cent in 1931. Since 1931 the percentage of early diagnoses has decreased from 16 to 12.9 per cent. This may represent only a relative decline, however, in view of the increasing use of sanatorium facilities for segregation of advanced, infectious cases of pulmonary tuberculosis. Formerly a number of sanatoriums attempted to limit their admissions to early cases but advances in treatment and a fuller realization of the importance of isolation as a control measure have helped to eliminate restrictions of this type.

A decrease in the percentage of first infection type of disease has apparently occurred, although it should be noted that 3,304 unclassified admissions to the preventorium group were not included in the foregoing study. Obviously, it would not have been accurate to assume that all these children were of the first infection type. Previous reports show that preventorium have accepted

are 97,632 patients included in this study: 6,081 first infection type, 10,301 minimal pulmonary tuberculosis, 25,740 moderately advanced, 44,047 far advanced, 4,678 nonpulmonary forms and 6,785 others.

From these data it is apparent that approximately 7 per cent of the patients are nontuberculous, while 93 per cent have some form of tuberculous infection. Of the cases of tuberculosis, 90,847 in all, 6.7 per cent were

not only the first infection type of tuberculosis but also nontuberculous patients, extra-pulmonary cases and occasionally the adult type of disease.

DIAGNOSTIC AND THERAPEUTIC FACILITIES

Tables 23 and 24 contain information concerning x-ray and laboratory departments, pneumothorax facilities and outpatient clinics in the tuberculosis departments and sanatoriums. From these data it would appear that the use of collapse therapy is steadily increasing, since 442 sanatoriums and 328 tuberculosis departments report facilities for artificial pneumothorax at present as compared to 406 sanatoriums and 101 departments in 1935. It is likewise encouraging to note that 361 sanatoriums and 222 departments have made further arrangements for the administration of collapse therapy in the outpatient clinics. All the federal sanatoriums have facilities for pneumothorax, sixteen state sanatoriums, 173 county, eighteen city, fourteen city and county and 151 private. Increases are noted in all these divisions except the municipal group, which reported the same number in 1935. Tuberculosis departments are likewise extending the use of collapse therapy, as evidenced by the presence of pneumothorax equipment in 237 general hospitals, thirty-nine mental institutions, twenty tuberculosis-isolation hospitals, and

classified as first infection type, 5.1 per cent as nonpulmonary forms and 88.2 per cent as frank pulmonary tuberculosis. In previous reports the corresponding figures were 8.7, 4.1 and 87 per cent respectively, while in 1931 the National Tuberculosis Association reported 8.4 and 88 per cent.

orthopedic unit and twenty-seven other departments. Special arrangements for an outpatient pneumothorax service have also been made in 189 departments of general hospitals, six mental institutions, fifteen tuberculosis-isolation hospitals, one orthopedic department and ten other units.

X-ray departments are now furnished in 410 sanatoriums and 568 tuberculosis departments, whereas in 1935 there were 368 sanatoriums in which roentgenographic or fluoroscopic facilities were available. All the

ments and physicians in charge in 224. Laboratory units were also present in 558 tuberculosis departments with 479 under medical supervision. The classification of laboratories by states and control will be found in tables 23 and 24. It can be added, however, that 403 tuberculosis departments in general hospitals have laboratory facilities, eighty-two in mental institutions, eighteen in tuberculosis-isolation hospitals and fifty-four in other departments including seven orthopedic units.

federal sanatoriums have x-ray departments, also sixty-eight state sanatoriums, 166 county, nineteen city, twelve city-county and 126 private. Three hundred and three indicated that physicians were in charge of the x-ray departments. Reference to table 24 will show that 509 of the x-ray services in the

tuberculosis departments, where 509 physicians were reported in charge. In the group of tuberculosis departments are 412 general hospitals that have roentgenologic equipment, eighty-six mental institutions, eighteen tuberculosis-isolation hospitals, eight orthopedic services and forty-three other departments.

In 1935 there were 346 sanatoriums that performed sputum examinations, 349 had facilities for blood counts and 378 had equipment for urinalysis. In the present survey 364 sanatoriums reported laboratory depart-

Community service in the form of outpatient tuberculosis clinics is now provided in 264 sanatoriums and 259 tuberculosis departments. Nineteen of the sanatoriums and thirteen of the departments report traveling or field clinics, yet it is not certain from the data supplied that the field clinics of the departments are in all instances associated with the tuberculosis service. Ten federal sanatoriums conduct tuberculosis clinics, forty-eight state, 126 county, nine municipal, nine city-county and sixty-two private sanatoriums.

NURSING PERSONNEL IN TUBERCULOSIS SANATORIUMS

Four hundred and fifty sanatoriums representing 69,330 beds and an average daily census of 60,511 reported 5,054 registered nurses employed, 1,223

unregistered nurses, 673 students and 4,389 attendants. Practical nurses are apparently included in both the unregistered and the attendant groups.

Further reference should be made to tables 25 and 26 showing nursing personnel in the tuberculosis sanatoriums classified by states and according to control. The number of nurses and attendants has also been included in the list of sanatoriums accompanying this report. The employment of students, including affiliates and postgraduate nurses, was reported by the following sanatoriums:

1. Arroyo-Del Valle Sanatorium, Livermore, Calif.
2. Barlow Sanatorium, Los Angeles.
3. Pauling Rest Home, San Fernando, Calif.
4. Santa Clara County Sanatorium, San Jose, Calif.
5. Expatriates' Tubercular Home, Denver.
6. Wildwood Sanatorium, Hartford, Conn.
7. William Wirt Winchester Hospital, West Haven, Conn.
8. The Outlook, Urbana, Ill.
9. Broadlawns, Polk County Public Hospital (Tuberculosis Department), Des Moines, Iowa.
10. Bangor Sanatorium, Bangor, Me.
11. Maryland Tuberculosis Sanatorium, Henryton, Md.
12. Maryland Tuberculosis Sanatorium, State Sanatorium, Md.
13. Hospital for Consumptives, Towson, Md.
14. Sanatorium Division of Boston City Hospital, Boston.
15. Rutland State Sanatorium, Rutland, Mass.
16. Rutland Training Center, Rutland, Mass.
17. Plymouth County Hospital, South Hanson, Mass.
18. Glen Lake Sanatorium, Oak Terrace, Minn.
19. Pokegama Sanatorium, Pokegama, Minn.
20. Mississippi State Tuberculosis Sanatorium, Sanatorium, Miss.
21. Mount St. Rose Sanatorium, St. Louis.
22. Hospital for the Tuberculous, Kearney, Neb.
23. Lakeland Sanatorium, Grenloch, N. J.
24. Hermann M. Biggs Memorial Hospital, Ithaca, N. Y.
25. Homer Folks Tuberculosis Hospital, Oneonta, N. Y.
26. Sea View Hospital, Staten Island, N. Y.
27. North Carolina Sanatorium for the Treatment of Tuberculosis, Sanatorium, N. C.
28. Hamilton County Tuberculosis Sanatorium, Cincinnati.
29. Eastern Oregon State Tuberculosis Hospital, The Dalles, Ore.
30. Beaver County Sanatorium, Monaca, Pa.
31. White Haven Sanatorium, White Haven, Pa.
32. State Tuberculosis Sanatorium, Sanatorium, Texas.
33. Piedmont Sanatorium, Burkeville, Va.
34. Catawba Sanatorium, Catawba Sanatorium, Va.
35. Blue Ridge Sanatorium, Charlottesville, Va.
36. King County Tuberculosis Hospital, Seattle, Wash.
37. Laurel Beach Sanatorium, Seattle, Wash.
38. Riverton Sanatorium, Seattle, Wash.
39. Muirdale Sanatorium, Wauwatosa, Wis.

HOSPITALIZATION OF CHILDREN

The survey of 1935 showed a total of 11,647 beds for children: 9,036 in the sanatoriums, 944 in the tuberculosis departments and 1,667 in the preventoriums.

Table 19.—Average Length of Stay in Tuberculosis Sanatoriums According to Control

Control	Patients Treated	Treatment Days	Average Stay (1938)	Average Stay (1934)
Federal.....	9,037	1,245,015	138	172
State.....	33,913	6,763,925	170	166
County.....	42,243	7,221,890	171	173
City.....	16,603	2,905,400	175	170
City-County.....	4,675	723,175	156	165
Private.....	23,800	3,500,715	147	151
	136,361	22,370,120	164	165

These figures are nearly identical with the present report of 11,717 beds, including 2,144 in the regular preventoriums, 8,285 in the sanatoriums and 1,288 in the tuberculosis departments. In all there were 169 sanatoriums, eighty-one tuberculosis departments and thirty-one preventoriums that reported beds available for the care of children. Included in the present bed capacity for children are 657 in federal hospitals, 2,467 in private institutions and 8,593 in the remaining tax-supported hospitals: state 3,014, county 3,570, municipal 1,308 and city-county 701. A similar classification of

beds in the sanatoriums, tuberculosis departments and preventoriums can be found in tables 27 and 28.

From the standpoint of bed capacity alone, it would appear that the tuberculosis service for children has remained practically unchanged. Reference to the pres-

167 tuberculosis departments and thirty-one preventoriums that accepted children for hospital care in 1935 it can be shown that a total of 13,400 children were admitted, 21,324 treated and 12,172 discharged. At the beginning of the year there were 7,924 patients pres-

ent; however, the average daily census was only 6,838. Admissions classified by control show the following distribution: federal 1,034, state 2,981, county 3,383, city 1,406, city-county 788, private 3,808. Similar data concerning the number of patients treated and the average daily census are included in table 28.

The sanatoriums admitted 8,332 children, discharged 7,500, treated 14,634 and maintained an average daily census of 5,382. The census at the beginning of the year was 6,302, at the end of the twelve months period 5,789. In the tuberculosis departments there were

of the sanatoriums that admit children. A total of 161 sanatoriums accepted "childhood" tuberculosis in 1934. In reporting on the condition of patients on admission, the sanatoriums listed 5,396 under the first infection type, the tuberculosis departments 685. It should be taken into consideration that adults with the first infection type are also included in these figures.

In recent years a number of institutions have discontinued their preventorium units in order to expand the regular sanatorium service. This would seem a logical procedure in view of the fact that the isolation of

Table 22.—Condition of Patients on Admission

1,764 children admitted, 2,496 treated and 1,368 discharged. The census averaged 566. It was 710 on the first day of the year, 640 on the last day. The preventorium, which had a daily census of 890, admitted 3,304 and treated 4,194.

The institutions classified as preventorium furnish less than half of the facilities now devoted to preventorium care. They have 2,144 beds, whereas the sanatoriums provide 2,447 and the tuberculosis departments 239. Accordingly there are at present 4,830 beds for preventorium purposes in thirty-one regular preventorium, fifty-five sanatoriums and thirteen tuberculosis departments. It is apparent that additional preventorium beds are available, however, since patients with the first infection type of disease were reported in 167

patients with open pulmonary tuberculosis has proved a more effective means of tuberculosis prevention and control than the hospitalization of tuberculous contacts and children with the first infection type of disease.

FEDERAL SANATORIUMS AND DEPARTMENTS

Included in the federal classification are forty-five tuberculosis institutions of the Indian Administration, eighteen Army hospitals, seven Naval hospitals, twenty under the control of the U. S. Public Health Service, fifty assigned to the U. S. Veterans Bureau and nine other federal departments. In all there are nineteen sanatoriums, 129 tuberculosis departments and one preventorium with a total capacity of 9,076 beds. The sanatoriums have 3,970 beds, the tuberculosis depart-

ments 5,026 and the preventoriums eighty. This is a decrease of 1,864 since 1935, when eighteen sanatoriums and 151 departments reported a combined capacity of 10,940 beds, including 328 for children. At present there are 657 beds for children with all but six assigned

toriums are in operation at present, thirty-two tuberculosis departments and one preventorium. These have a capacity of 1,609 including 651 beds for children. The Sioux Sanatorium, Rapid City, S. D., has been added to the list since the previous survey, and the Kayenta

to the Indian Service. As shown in table 29, the federal institutions admitted 14,900 patients in 1938, treated 21,883 and maintained an average daily census of 6,703. The former report showed an admission rate of 15,523.

In 1935 the Indian Administration reported eleven sanatoriums and forty-one tuberculosis departments with a total capacity of 1,471 beds. Twelve sana-

Sanatorium, Kayenta, Ariz., was transferred from the departments to the sanatorium classification. However, the Fort Defiance Sanatorium, Fort Defiance, Ariz., became a unit of the Navajo General Hospital and was accordingly listed as a department. Although the bed capacity has increased, the scope of the clinical service remains practically unchanged. The admissions, totaling 2,626, are almost identical with the report of 1935.

but the average daily census has increased from 1,028 to 1,185. There were 3,644 patients treated with 116 days as the average length of stay. Vacancies totaled 480, patients on the waiting list 180. Thirty-nine of the institutions in this group report x-ray departments,

ments. Formerly there were 783 beds available in one sanatorium and twenty-five departments. An increase occurred in the number of admissions and also in the average daily census. Admissions totaled 1,002 and the average occupancy 585 as compared to 738 and 398 in 1934. X-ray and laboratory facilities are furnished in all the institutions in this group. Seventeen have pneumothorax equipment and twelve indicate that collapse therapy is made available to outpatients.

In the Veterans hospitals there has been a considerable decrease in the number of beds for tuberculosis. While the previous report showed six sanatoriums and fifty-nine tuberculosis departments with a capacity of 7,734 beds, the present survey reveals only 5,671 in forty-four departments and six hospitals that limit their service to tuberculosis. The sanatoriums have 2,713 beds, the tuberculosis departments 2,958. There has also been a decrease in the number of admissions from 10,493 to 9,099. On the other hand the reports indicate an increase in the average daily occupancy when compared with the data supplied in 1934. All the Veterans hospitals included in this study have x-ray and laboratory departments, thirty-six have pneumothorax equipment and thirty provide facilities for outpatient pneumothorax service.

There are nine other federal hospitals that report 216 beds for tuberculosis, 279 admissions and an average daily census of 111. These institutions also have x-ray and laboratory facilities and four furnish equipment for collapse therapy.

STATE SANATORIUMS

At present there are seventy-two state sanatoriums with a total capacity of 21,066 beds: 18,203 for adults and 2,863 for children, including 656 preventorium beds. This represents a net increase of seven institutions and 3,758 beds since the report of 1935. With the addition of new institutions in Arizona, Florida, New Mexico and Utah there are now forty states that own and operate sanatoriums for the treatment of tuberculosis. In Kansas, Michigan, North Carolina and Texas new units have also been added to supplement previous facilities, whereas in Oklahoma a change in service

thirty-six have laboratory units and twenty-four provide pneumothorax equipment.

In the previous survey, thirteen hospitals of the U. S. Army reported 630 beds for tuberculosis and 1,197 admissions. At present there are eighteen tuberculosis departments, 617 beds and an annual admission rate of 1,817. Information concerning the average daily occupancy is incomplete, however, but the census at the beginning of the year was 446. All these hospitals have x-ray and laboratory departments, and five supply facilities for the administration of pneumothorax.

Naval hospitals report seven tuberculosis departments, 152 beds for tuberculosis, 177 admissions and an average daily census of 100. All indicate that facilities are available for pneumothorax and laboratory and x-ray service. In 1935 there were ten tuberculosis departments, 176 beds and 351 admissions in this group.

In the hospitals of the United States Public Health Service there are 811 beds for tuberculosis: 244 in a sanatorium and 567 in nineteen tuberculosis depart-

necessitated the reclassification of one of the state sanatoriums as a tuberculosis department. The additions to the list include the State Welfare Sanatorium, Tempe, Ariz., the Florida State Sanatorium, Orlando, Fla., Kenney Memorial Hospital, Norton, Kan., Northern Michigan Tuberculosis Sanatorium, Gaylord, Mich., State Tuberculosis Sanatorium, Socorro, N. M., Western North Carolina Sanatorium, Black Mountain,

N. C., Kerrville State Sanatorium, Kerrville, Texas, and the Utah State Tuberculosis Sanatorium, Ogden, Utah. The Soldiers' Tubercular Sanatorium, Sulphur, Okla., was transferred from the sanatorium to the department list.

As shown in table 30, the state sanatoriums admitted 21,917 patients: 18,173 adults, 2,716 children and 1,028 unclassified. A total of 39,986 patients were treated during the year. At the end of the twelve months period there were 18,889 patients under treatment and

At present there are eighty-five sanatoriums and hospitals approved for residencies in tuberculosis. These include fifteen state sanatoriums, as indicated by the plus sign (+) in the accompanying list of tuberculosis institutions.

COUNTY SANATORIUMS

The county sanatoriums, now constituting the largest group of tuberculosis institutions, show a net increase of ten since the previous survey. Seventeen institutions have been added to the list, six have been discontinued

a waiting list of 4,992 in comparison to 2,177 vacancies. The average daily census was 18,448, the average length of stay 170.

Facilities for pneumothorax are now available in sixty-seven of the state sanatoriums, and fifty-seven have made arrangements for collapse therapy in the outpatient department. Sixty-eight have x-ray equipment, sixty-five provide laboratory facilities and forty-eight conduct tuberculosis clinics. Field clinics are also sponsored by seven of the institutions in this group.

The nursing personnel consists of 1,173 registered nurses, 382 other graduates, 274 students and 1,252 attendants. The student nurses are distributed in twelve training schools.

and one has been reclassified as a tuberculosis department. The additions include the Morgan County Tuberculosis Sanatorium, Flint, Ala.; Batson Memorial Sanatorium, Lafayette, Ala.; Pauling Rest Home, San Fernando, Calif.; San Luis Obispo County Tuberculosis Sanatorium, San Luis Obispo, Calif.; Lake County Sanatorium, Waukegan, Ill.; Hillcrest Tuberculosis Hospital, Vincennes, Ind.; Kenton County Tuberculosis Hospital, Covington, Ky.; Ontonagon County Sanatorium, Rockland, Mich.; Jones County Cottage Sanatorium, Ellisville, Miss.; Hinds County Tuberculosis Sanatorium, Raymond, Miss.; Hudson County Tuberculosis Sanatorium, Jersey City, N. J.; Roosevelt Hospital, Metuchen, N. J.; Tuscarawas County

Sanatorium, New Philadelphia, Ohio; William Roche Memorial Tuberculosis Hospital, Toledo, Ohio; Erie County Tuberculosis Hospital, Erie, Pa.; Bexar County Tuberculosis Colony, Southton, Texas, and the Blue Mountain Sanatorium, Walla Walla, Wash.

The Pima County Hospital, Tucson, Ariz., is now listed under tuberculosis departments, whereas the following sanatoriums have discontinued their service: Maricopa County Tuberculosis Hospital, Phoenix, Ariz.; Bon Air Tuberculosis Sanatorium, Ontonagon, Mich.; Greene County Tuberculosis Sanatorium, Springfield, Mo.; Pleasant Valley Sanatorium, Bath, N. Y.; Tompkins County Tuberculosis Hospital, Trumansburg, N. Y., and the Lucas County Tuberculosis Hospital, Toledo, Ohio.

the outpatient departments. One hundred and twenty-six report tuberculosis clinics within the institution and it was also indicated that nine conduct an outpatient service in the field.

Registered nurses total 1,734, other graduates 356, student nurses eighty-seven and attendants 1,423. Thirteen of the sanatoriums in this group participate in the training of student nurses. It is also of interest to note that twenty-four county sanatoriums have been approved for residencies in tuberculosis.

MUNICIPAL SANATORIUMS

The District of Columbia and the states of Illinois, Massachusetts, Michigan, Missouri, New York, Ohio, Pennsylvania and Virginia have sanatoriums under

Indian Administration: 1 Preventorium, 80 beds; 100 admissions, 63 average census.

There are at present twenty-six states in which sanatoriums are operated under county control, the same number as reported in 1935. At that time, however, Arizona was included but not the state of Mississippi.

In table 31 it can be noted that 182 county sanatoriums provide 22,206 beds: 19,500 for adults and 2,706 for children. This represents an increase of 2,092 since the previous survey. Of the beds for children 1,050 are utilized for preventorium care. Admissions total 22,778, patients treated 42,243, the average daily census 19,481 and patients under treatment at the end of the year 19,521. The number of patients on the waiting list was 1,095, although vacancies totaled 2,685. In these institutions the average length of stay was 171 days.

One hundred and sixty-six of the county sanatoriums have x-ray departments, 145 have laboratory facilities and 173 provide pneumothorax equipment. Collapse therapy has also been extended into 158 of

municipal control. Since the previous survey, which showed twenty-two institutions in this group, there have been three sanatoriums added, four removed and one transferred to the list of tuberculosis departments. The additions include the Municipal Tuberculosis Home, North Riverside, Ill., the Rockford Municipal Sanatorium, Rockford, Ill., and the Cleveland Tuberculosis Sanatorium at Warrensville, Ohio, formerly classified as city-county institutions. Three institutions discontinued their service: the Health Department Hospital, Chicopee, Mass.; the Holyoke Tuberculosis Sanatorium, Holyoke, Mass., and the Convalescent Tuberculosis Hospital, Cleveland. The Tuberculosis Hospital, Washington, D. C., was also removed from the list, since it has now been combined with the Tuberculosis Sanatorium at Glenn Dale, Md. Formerly the Tuberculosis Department of Baltimore City Hospital was also included but has now been reclassified as a tuberculosis department.

Accordingly there are now twenty municipal sanatoriums in operation with a total capacity of 8,486 beds, including 1,149 beds for children. Reference to the corresponding section of the 1935 report will indicate that the bed capacity has increased by 1,121 even though the number of institutions has decreased.

The municipal sanatoriums admitted 8,993 patients, treated 16,603 and maintained an average daily census of 7,960. The average length of stay was 175 days. At the end of the twelve months period there were 8,008 patients under treatment, 207 on the waiting list and 478 vacancies.

Diagnostic and therapeutic facilities are provided as follows: x-ray departments nineteen, clinical labora-

however, so that there are still eleven states that have sanatoriums under city-county control. The additions to the list include the Escambia County Tuberculosis Sanatorium, Pensacola, Fla.; the Negro Tuberculosis Hospital, Jacksonville, Fla., and the Wake County Tuberculosis Sanatorium, Raleigh, N. C. Two sanatoriums formerly included in this group have been transferred to the municipal classification, namely the Rockford Municipal Sanatorium, Rockford, Ill., and the Sunny Acres, Cleveland Tuberculosis Sanatorium, Warrensville, Ohio.

The city-county sanatoriums have a total capacity of 2,191 beds, a decrease of 232 since the last report. There are 1,755 beds for adults and 436 for children,

* Partly unclassified.

tories thirteen, tuberculosis clinics nine. Of eighteen sanatoriums equipped for the administration of pneumothorax, thirteen have made arrangements for collapse therapy in the outpatient department.

The reports indicate that only one of the municipal sanatoriums offers facilities for the training of nurses. Listed in the nursing division are eighteen students, 963 registered nurses, 116 unregistered graduates and 451 attendants. Eight institutions in this group are approved by the American Medical Association for residencies in tuberculosis.

CITY-COUNTY SANATORIUMS

In 1935 there were fifteen city-county sanatoriums in operation in eleven states. Sixteen institutions are reported in the present survey, but two of the states are no longer represented on the list, namely Illinois and Ohio. Florida and North Carolina have been added,

including 309 for preventorium care. The following statistical data illustrate the extent of tuberculosis hospitalization in this division: admissions 2,712, patients treated 4,675, average daily census 1,995, census at end of year 1,996, average length of stay 156 days, waiting list 301, number of vacancies 195. Reference should be made to table 33.

Fourteen sanatoriums provide pneumothorax facilities for inpatients and eleven for outpatients, twelve have x-ray departments and eleven report laboratory units. Tuberculosis clinics are now conducted in nine of these institutions.

Ninety-two registered nurses are employed, forty unregistered graduates and 173 attendants.

PRIVATE SANATORIUMS

The greatest reduction in the number of tuberculosis sanatoriums has occurred in the private group, where

there are now 170 institutions as compared to 178 in 1935. At present there are thirty-two states where sanatoriums are operated under private control; formerly also the state of Georgia was included. By comparison with the previous report it will be noted that eighteen sanatoriums have since been added to the list, whereas twenty-seven have been removed.

Additions occurred in the states of Alabama, California, Connecticut, Florida, Louisiana, Massachusetts, Michigan, New Mexico, New York, Ohio, Texas and Virginia. During the same period twenty-seven sanatorium services were discontinued or reclassified in Arizona, California, Colorado, Georgia, Illinois, New Jersey, New Mexico, New York, North Carolina, Pennsylvania, Tennessee, Texas and Washington.

The private sanatoriums represent various types of ownership and control and differ widely in size and completeness of hospital service. Their average capac-

administration of pneumothorax, including 104 that have also made provisions for an outpatient pneumothorax service.

It has been shown that thirteen of these institutions employ student nurses. Altogether the nursing personnel consists of 720 registered nurses, 317 unregistered graduates, 294 students and 593 attendants. It can also be reported that thirteen of the private sanatoriums have qualified for residency approval in tuberculosis.

TUBERCULOSIS DEPARTMENTS

It has been shown in the present report that 630 tuberculosis departments supplement the facilities of the sanatorium division. In addition there is another group of 584 hospitals that admit tuberculous patients or conduct tuberculosis clinics yet do not have an inpatient service that can be classified as a departmental unit. The latter include 533 general hospitals,

ity is the lowest of any of the sanatorium groups, being only seventy-four beds. The state sanatoriums average 293, the county 122, the municipal 424 and the city-county sanatoriums 137. The present capacity is 12,794 beds, as compared to 13,864 in 1935. Included are 11,996 beds for adults and 798 for children with 296 allocated to preventorium care.

Although the number of institutions and the bed capacity have decreased there has been no corresponding reduction in the clinical service. On the contrary there has been a slight increase in patient personnel, as indicated in table 34. The admissions total 14,644, the number of patients treated 23,890 and the average daily census 9,591. In 1935 the corresponding figures were 14,480, 21,104 and 9,490. At the end of the year the private sanatoriums had 750 on the waiting list with vacancies totaling 3,537. A slight reduction occurred in the average length of stay, which is now reported as 147 days.

Of 170 sanatoriums in this group 126 have x-ray departments, 111 have laboratory facilities and sixty-two conduct tuberculosis clinics. One hundred and fifty-one private sanatoriums have facilities for the

eleven mental institutions, three tuberculosis-isolation units, four orthopedic services and thirty-three other hospitals. Classified by control they comprise eighty federal, thirty-three state, twenty-four county, twenty-eight city, five city-county and 414 private hospitals.

Table 35 presents a summary of the tuberculosis service in hospitals that do not fall within the sanatorium classification. This shows that 439 of the 630 tuberculosis departments are in general hospitals, ninety-two in mental institutions, twenty-six in tuberculosis-isolation units, eight in orthopedic hospitals and sixty-five in other divisions.

The general hospitals have 14,824 beds for the treatment of tuberculosis, 13,939 for adults and 885 for children. On comparison with the previous report it is noted that the number of departments has increased by twenty and the bed capacity by 356. The annual admissions showed a decrease, however, from 37,124 to 34,739. Reference should be made to table 9, in which a further classification of admissions is given in accordance with the type of institutional control. The number of patients treated was 46,036, the average daily occupancy 10,119 and the census at the

beginning of the year 11,295. In 1934 the tuberculosis departments of general hospitals had 11,318 patients under treatment on the day of reporting. Of particular interest is the report that 237 of the general hospitals are now in position to administer pneumothorax; twenty-eight other hospitals in the general group indicated also that pneumothorax facilities are available.

The extension of the tuberculosis service into the general hospital field has received the endorsement of the American Medical Association, the American Hospital Association and the National Tuberculosis Association. Services of this type should be under the supervision of physicians competent in this field and should provide proper nursing technic and adequate segregation to prevent the spread of infection to other patients and

ther statistical data concerning the scope of service. It is shown that twenty-one furnish pneumothorax equipment, nineteen have x-ray departments, nineteen provide laboratory facilities and ten conduct tuberculosis clinics. When classified by control, these institutions exhibit the following distribution: county five, city twenty, city-county one. Twenty-six hospitals were likewise included in 1935 but three of the original group are no longer listed, whereas the following institutions have been added: Niagara Falls Municipal Hospital, Niagara Falls, N. Y.; Schenectady City Hospital, Schenectady, N. Y., and the Philadelphia Hospital for Contagious Diseases, Philadelphia.

It would seem that the information concerning tuberculosis departments in nervous and mental hospitals is

* Partly unclassified.

hospital personnel. The fact that tuberculous patients are now accepted in at least 971 general hospitals would seem to emphasize the need for adequate isolation facilities. These could be utilized not only in the treatment of tuberculosis but also for the removal of other infectious diseases from the open wards.

The tuberculosis-isolation hospitals offer a combined service in tuberculosis and contagious diseases. Their total capacity is 7,144 beds, of which 2,813 are assigned to the tuberculosis division. As compared with the previous report, this indicates an increase of 257 beds. The number of admissions decreased, however, from 4,456 to 4,112 but the average daily occupancy increased from 2,134 to 2,448. At the end of the twelve months period there were 2,365 patients under treatment.

The list accompanying this report contains the names of twenty-six tuberculosis-isolation hospitals and fur-

incomplete even though reports were received from practically all of the institutions in this field. Apparently some of the hospitals failed to indicate their facilities for tuberculosis, since only ninety-two departments were reported as compared to 193 in the previous survey. Although the centralization of tuberculosis service has already been noted in some of the state hospitals, it would not appear that this factor alone could be responsible for a reduction of over 50 per cent in the number of institutions treating tuberculous insane. Census reports show a similar decrease especially at the end of the twelve months period, when the number of patients under treatment was 4,743 as compared to 9,321 in 1934.

The tuberculosis departments in mental hospitals report 7,189 beds at present, 1,874 patients admitted during the year and an average daily occupancy of 3,858. The previous survey listed 9,478 beds and

2,425 admissions. In mental institutions the segregation of tuberculous patients is especially important to prevent the spread of infection in crowded wards. Separate departments are therefore considered necessary to facilitate the institutional control of tuberculosis and the application of scientific therapy. In this connection it is of interest to note that thirty-six psychiatric hospitals have supplied facilities for the administration of pneumothorax.

For comparative data concerning orthopedic hospitals and other departments, reference should be made to table 35 in the present report and to table 32 of the previous survey.

One hundred and twenty-six tuberculosis departments under state control report 7,633 beds, 4,781 admissions, 9,748 patients treated and a census of

representing 99 per cent of the total bed capacity of all registered hospitals.

2. The statistical data included in this report cover a twelve months period ended either Sept. 30 or Dec. 31, 1938.

3. Included in the present study are 479 sanatoriums, 630 tuberculosis departments and thirty-one preventoriums, a total of 1,140 institutions.

4. The sanatorium group contains nineteen federal, seventy-two state, 182 county, twenty municipal, sixteen city-county and 170 private sanatoriums.

5. The tuberculosis departments are located in 439 general hospitals, ninety-two mental institutions, twenty-six tuberculosis-isolation hospitals, eight orthopedic units and sixty-five hospital departments of

5,012 at the end of the year. The county departments, sixty-two in all, have 4,144 beds. They admitted 5,637 patients and treated 8,586. Their census at the end of the twelve months period was 3,017. In sixty-two municipal departments there were 5,273 beds reported, 13,839 admissions, 18,401 patients treated and 4,990 patients under treatment at the time of reporting. The bed capacity in seven departments under city-county management is 1,160. These units had 1,915 admissions in 1938, a total of 2,886 patients treated and 1,011 under treatment at the end of the year. In 244 private departments the bed capacity was 2,708, the annual admission rate 6,880 and the number of patients treated 8,999. The census on the last day of the twelve months period was 1,916.

SUMMARY

1. The present report of tuberculosis facilities in the United States supplements the survey of 1933-1935. It is based on information received from 5,950 hospitals

prisons, reformatories, convalescent units and other institutions.

6. There are at present 98,801 beds for tuberculosis, 87,084 for adults and 11,717 for children. The sanatoriums have 70,713 beds, the tuberculosis departments 25,944 and the preventoriums 2,144. In 1935 a total of 95,198 beds were reported, including 11,647 for children.

7. Included in the beds for children are 4,830 for preventorium care. The sanatoriums furnish 2,447 beds for this purpose, the tuberculosis departments 239 and the regular preventoriums 2,144.

8. The sanatoriums, tuberculosis departments and preventoriums admitted 122,342 patients during a twelve months period, discharged 120,366, treated 202,021 and maintained an average occupancy of 79,300. The census at the beginning of the year was 79,679, on the last day 80,403. In 1934 there were 121,706 patients admitted and 81,652 patients present on the day of reporting.

9. The number of children admitted was 13,400, including 8,332 in the sanatoriums, 1,764 in the tuberculosis departments and 3,304 in the preventoriums. The previous survey reported 15,523.

10. The average length of stay in the tuberculosis sanatoriums was 164 days as compared to 166 in 1934. In the tuberculosis departments the average was identical with the previous report of 101 days.

11. The report indicates that 93 per cent of the patients had some form of tuberculous infection. Of

in 361 of the sanatoriums and 222 of the tuberculosis departments. This represents an appreciable increase in the facilities for collapse therapy.

14. Roentgenologic service is available in 410 sanatoriums and 568 tuberculosis departments. In the previous survey, 368 sanatoriums reported x-ray facilities.

15. The present report indicates that 364 sanatoriums and 558 tuberculosis departments have laboratory departments. Apparently no marked change has occurred in this phase of the sanatorium service.

this group 6.7 per cent were classified as first infection type, 5.1 per cent as nonpulmonary forms and 88.2 per cent as frank pulmonary tuberculosis. Pulmonary cases of the reinfection type showed the following condition on admission: minimal 12.9 per cent, moderately advanced 32.1 per cent and far advanced 55 per cent. In 1934 the corresponding ratios were 13.1, 29.7 and 57.2 per cent.

12. The waiting list totals 8,797, the number of vacancies 16,254. In the state and city-county sanatoriums and the municipal tuberculosis departments the waiting list exceeds the number of vacancies.

13. Equipment for pneumothorax is provided by 442 sanatoriums and 328 tuberculosis departments. Facilities for outpatient pneumothorax are also included

16. Outpatient clinics are now conducted in 264 sanatoriums and 259 tuberculosis departments. Nineteen of the sanatoriums and thirteen of the departments report field clinics.

17. It is hoped that the present report will prove useful to the medical profession and other agencies interested in the prevention, treatment and control of tuberculosis. For comparative data, reference should be made to the survey of 1935.

The preparation of this report would not have been possible without the assistance of the hospital and sanatorium superintendents, whose helpful cooperation in supplying accurate and complete information is highly appreciated. Acknowledgment is also made of the cooperation extended by the National Tuberculosis Association.

SATURDAY, MARCH 2, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE TUBERCULIN TEST AND X-RAYS IN MASS SURVEYS FOR TUBERCULOSIS

Tuberculin have been used successfully in the detection of primary and calcified tuberculous lesions for a generation. Nevertheless, discussion¹ still seeks to clarify their value, limitations and relation to the more accurate x-ray film. The problem is less one of ascertaining how many persons have been infected in a given community than to select for more careful study a relatively small number of suspected persons from a large number of people who are presumably well; especially is it important to isolate those with really active pulmonary lesions. In view of the general decline of tuberculosis and the lessened opportunity for reinfection, the

number of nonreactors to tuberculin may be expected to increase. Whether or not the percentage of the tuberculin positive in a community will decline proportionately with the death rate is problematic. Conceivably, tuberculin reactions may eventually become negative in all cases of calcified primary lesions if further infection does not occur.

The overwhelming majority of patients with frank tuberculosis react even to small doses of most tuberculins on the market. It is claimed that proved records do not exist of the development of the disease in the absence of a positive reaction and consequently that a negative tuberculin test excludes active tuberculosis with a high degree of probability. Tuberculin tests are regarded by individual proponents as diagnostically reliable in from 90 to 95 per cent of primary and calcified lesions in mass surveys in which special hazards do not exist. The failure to disclose the residual cases is attributed chiefly to the fact that persons previously tuberculin positive become tuberculin negative. Among 2,490 persons examined by the staff of the Henry Phipps Institute of the University of Pennsylvania and found positive to tuberculin on the first or a subsequent examination, 276 (11 per cent) became negative either transiently or for the remainder of the period of observation. The initial intensity of the disease and the degree of household exposure had much to do with the waning allergy. Tuberculin anergy in certain well known clinical conditions does not enter into the discussion. The conviction that the tuberculin test is rarely negative in the presence of significant tuberculosis acquires support from a survey of 500 adults tested at the Herman Kiefer Hospital, Detroit, with the x-rays in which nine failed to respond to the usual doses. Retesting by means of 10 mg. of old tuberculin brought out one more positive response. All of the nonreactors, except one, had the disease in the terminal stage. On the other hand, in a survey of 4,271 white persons with calcifications but without evidence of manifest tuberculosis conducted in Giles County, Tenn., the incidence of a tuberculin-negative response was 34.2 per cent. This lack of tuberculous specificity occurred at all ages. Results like these clearly place the burden of proof on the determination that all such lesions are tuberculous.

Tuberculin allergy may be so universal in adolescents and adults in certain geographic areas such as Puerto Rico that the tuberculin test has little validity beyond the age of 10. Possibly in mass surveys a large number of the population may refuse the needle, as in the survey at Hagerstown, Md., where 40 per cent voiced their refusal. It is conceded that tuberculin tests are unusually advantageous in infants because of the difficulty of securing uniformly good x-ray films of the chest. Their usefulness for control purposes is challenged in school children and adolescents because of the low incidence of active disease compared with the number of infections.

1. Long, Esmond R.; Douglas, Bruce, H.; Doull, James A.; Dearing, W. Palmer; Ianne, Charles L., and Pastor, J. Rodriguez: A Symposium on Mass Tuberculin Testing and X-Raying, *Am. Rev. Tuberc.* 40: 607 (Dec.) 1939.

In 1,542 school children between the ages of 10 and 19 given the tuberculin test in Philadelphia, only fourteen cases of "manifest tuberculosis" were discovered, a ratio of 108 to 1. Single dose Mantoux testing is regarded by one investigator as a reasonably effective screen for case finding when the cost limits the number of x-ray examinations. Criticisms voiced against defects inherent in tuberculin testing, such as lack of standardization of tuberculin preparations, lack of uniformity of dosage and the varying classifications of the degree of reaction, are not new and will speed improvements of the technic.

The x-ray film is still the basic tool in case finding. An x-ray examination can be carried out with less inconvenience to the public and requires fewer visits. It possesses greater accuracy. The cost, to be sure, is greater. It is not free from certain imperfections, for it may reveal too much and again too little. Interference with accuracy may arise from the fact that not all calcium deposits discovered are tuberculous or that a complete view of the lung field may be obstructed by mediastinal and heart shadows or be due to the lack of experience required to interpret the film correctly. Ordinary lesions may often be present elsewhere than in the visual pulmonary field and reinfection may be hidden. The x-ray film, moreover, does not reveal infection until after it has caused a shadow in the lung. An instance is cited from the Santa Clara County Sanatorium at San Jose, Calif., in which a pregnant woman negative on x-ray examination proved positive to the tuberculin test. Further examination revealed that the husband harbored an occult minimal tuberculosis with positive sputum. A legitimate inference would be that a man's prophylaxis against tuberculosis, like his education, should begin before he is born. Only two deaths from tuberculosis in the first year of life have been reported since 1934 for Santa Clara County, with a mixed urban and rural population of 160,000. Early diagnosis permitted the early institution of collapse therapy and a normal pregnancy without extension of the pulmonary disease.

New types of x-ray examination intended to reduce the cost of mass surveys, such as the fluoroscope, sensitized paper, the use of 14 by 14 films instead of the usual 14 by 17 (resulting in a saving of 20 per cent in film cost) and miniature chest films made by photographing the fluoroscopic image on 4 by 5 inch films, offer inviting prospects of economy. The praise of the fluoroscope is sung as a case-finding mechanism for the geographic area in which tuberculin allergy in adolescents and adults is universal, and fluoroscopes are reported to be installed in every public health unit. A leading insurance company known for its investigations in public health is reported as having made fluoroscopic examinations of 25,000 persons at an average cost of 15 cents. It also found that an accurate diagnosis as to the presence or absence of pulmonary tuberculosis could be made with the fluoroscope alone in 87 per cent of

2,603 persons examined. In a cooperative survey made by the Michigan State Health Department, the U. S. Public Health Service and the Michigan Sugar Beet Growers Association, 4,000 Mexicans to be transported for summer work were examined with the newest type of portable fluoroscope and eighty-one cases of pulmonary tuberculosis were discovered. When the less expensive methods of x-ray examinations are perfected, the tuberculin test may be confined to the determination of tuberculous infections in infants and young children and to cases of atypical lesions in adults harboring tubercle bacilli. In doubtful cases, confirmation will continue to be sought in tuberculin, sputum analysis and other clinical evidence. Preliminary tuberculin screening may continue to hold the field for some time.

ALLERGY AND ANAPHYLAXIS IN TUBERCULOSIS

The debated question as to whether allergic and anaphylactic manifestations in experimental tuberculosis are basically similar or different has been reinvestigated by Corper.¹ His results strongly support the view that the phenomena are of fundamentally different nature. Significant facts partly here reported and partly cited seem to establish the following facts: Guinea pigs which receive intravenous injections of protein from tubercle bacilli are sensitized so that typical anaphylactic shock is caused by later injection of this protein. The sensitization can be transferred passively to normal guinea pigs with the blood. However, guinea pigs rendered "allergic" by infection with a strain of tubercle bacilli of low virulence do not demonstrate the characteristic anaphylactic type of hypersensitiveness when injected with the tuberculoprotein. In appropriate amounts the latter will kill such pigs, but only after several hours, a type of death in clear contrast to the rapidly occurring death of anaphylaxis.

By an ingenious experiment Corper was able to induce the two types of sensitization in the same animal. In a typical experiment a pair of guinea pigs were made allergically sensitive by infection with a millionth of a milligram of virulent human type tubercle bacilli. One of these had previously been given an anaphylactically sensitizing dose of tuberculoprotein. Three months after the infection with tubercle bacilli each pig was given 0.8 mg. of tuberculoprotein. The animal not sensitized before its injection died five hours later from the general reaction characteristic of allergy in the skin-sensitive animal. The other was thrown immediately into acute anaphylactic shock but recovered, only to die from the more protracted shock characteristic of allergic response and in exactly the same length of time as the other animal.

1. Corper, H. J.: Analysis of the Tubercle Bacillus and Its Natural Products by Immune, Allergic and Anaphylactic Tests, *J. Infect. Dis.* 66:23 (Jan.-Feb.) 1940.

Naturally such an experiment should be repeated to make certain that the result can be considered a constant phenomenon. Corper's report, however, adds new evidence to the growing view that tuberculin allergy and anaphylactic shock are basically different. The results have definite connotations for our understanding of resistance, for, as he points out, the allergic sensitization is at least associated with increased resistance to infection, whereas animals sensitized only anaphylactically, by injection of the protein without infection, display no increased resistance. For the latter the bacillary body seems vital.

Current Comment

TUBERCULOSIS HOSPITALIZATION

In the survey of tuberculosis hospitalization by the Council on Medical Education and Hospitals published in this issue of *THE JOURNAL*, it is shown that the sanatoriums, tuberculosis departments and preventoriums admitted 122,342 patients in 1938, treated 202,021 and maintained an average daily census of 79,300. This represents an annual expenditure of over seventy million dollars for hospital care, not including the loss of earning power of the patients or the care of dependents. Tuberculosis is therefore still a great economic problem. The survey reveals also an increasing use of sanatorium facilities for far advanced cases, a trend which will aid in decreasing dangerous foci of infection. However, the continued hospitalization of nontuberculous children in some of the sanatoriums for adult tuberculosis is fraught with danger if separate units are not maintained. When additional beds are required for the care of patients it would seem logical to convert preventorium units to sanatorium use, for the isolation of open cases has proved more effective in the prophylaxis of tuberculosis than the hospitalization of tuberculous contacts. There are 98,801 beds available in this country for tuberculous patients, including 4,830 assigned to preventorium care. While additional beds are needed in various communities, the evaluation of sanatorium needs can better be assigned to members of the medical profession and other agencies familiar with local conditions. Institutional care is a vital factor in the prevention and treatment of tuberculosis. From an epidemiologic point of view, segregation and therapy accomplish the same result in removing foci of infection from the community, and that is the essence of tuberculosis control.

INTERNAL PRESSURE WAVES OF MUSCLE MOTION

To the physician abnormal spasms and dystrophy of muscles are significant in diagnosis. The tone of muscle is an index of health. Any contribution to the underlying mechanics of motion in muscles is clinically significant. A full explanation of muscular contraction involves research in histology, physiology, chemistry, roentgenology and other fields. There is no adequate explanation at present of the mechanism by which shortening, firmness and strength of muscle are pro-

duced, the nature of the energy thus transformed into mechanical work and the relation of this energy to the chemical reactions that take place in the stimulated muscle. The measurable manifestations of energy that are observed in the contracting muscle are the changes in chemical constitution, electrical potential, heat and mechanical work. The purely physiologic approach to the problem of motion in muscles pushes the refinements of analysis into time rather than space. Even if one knew precisely at what stage the chemical energy that is transformed into mechanical work is liberated one would still fail to know the actual machinery of contraction. The histologic method has made little advance in our knowledge of the structure of muscle during relative rest and variable degrees of motion. The recent demonstrations by Carey¹ that there is multiplication of the transverse muscle striae associated with a sudden rise in temperature within physiologic limits and that prolonged cooling results in subtraction point to an intimate association between these periodic muscle structures and the rate of rhythmic chemical change. The muscle striae are apparently not fixed static membranes but are the structural expressions of an underlying dynamic mechanism. Carey and Zeit,² furthermore, have demonstrated that the strongly active muscle fibers have their inorganic salts arranged in an alternate series of waves of condensations and rarefactions. Elsewhere in this issue of *THE JOURNAL*, Carey³ presents additional experimental evidence that different chemical reactions in gels confined within microscopic capillary glass tubules with dimensions approaching those of a skeletal muscle fiber are associated with periodic stratifications similar in arrangement and number to the cross striae and contraction waves in smooth and skeletal muscles. He observes a moving explosive wave front in the microcapillary glass tubules which he interprets as a result of the multiple microscopic pressure waves associated with the periodic mass action of chemical changes. The phenomenon of "interference," which is a crucial test of wave mechanics, appears to be demonstrated for both the striae in muscle and those in gels confined in microscopic glass tubules under adequate physical and chemical conditions. If future research confirms these observations and interpretations, a start will have been made in bridging the important gap in normal and abnormal muscle motions as regards the means by which chemical energy is transformed into mechanical energy. There appear to be concomitant microscopic waves of internal compression associated with chemical reactions. The detection of these micromechanical waves is dependent on confining the chemical reactions of the gel within a microcapillary tubular space which orients and concentrates the pressure waves expressed as alternate dark and light bands of variable number and patterns in both microscopic glass tubules and muscle fibers and fibrils.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—S. 685, proposing to create a Bureau of Water Pollution Control in the Public Health Service, passed the Senate May 1, 1939, and was thereafter reported to the House of Representatives with recommendation that it pass. Among other things, this bill provided for federal grants-in-aid to assist states, municipalities and public bodies to construct treatment works to prevent pollution of navigable waters. On February 20 the House Committee on Rivers and Harbors recommended in a supplemental report that the grants-in-aid provision be stricken from the bill and that there be substituted an authorization whereby the Reconstruction Finance Corporation may make loans to finance the construction of treatment works.

Bills Introduced.—S. 3415, introduced by Senator Schwelienbach, Washington, proposes to authorize the Secretary of Interior to establish, construct, equip and operate a hospital for the legally adjudged insane of Alaska, the hospital to be constructed at Bellingham, Wash. H. R. 8378, introduced by Representative Lea, California, proposes that the Secretary of Labor be directed to cancel the outstanding order and warrant of deportation in the case of Dr. Filiberto A. Bonaventura. H. R. 8542, introduced, by request, by Representative May, Kentucky, proposes to authorize the appointment of female dietitians and female physical therapy aides in the Medical Department of the Army. H. R. 8547, introduced by Representative Starnes, Alabama, proposes to authorize loans to public bodies and nonprofit organizations for hospital, water, sewer, stream pollution control and related projects and facilities. H. R. 8613, introduced by Representative Van Zandt, Pennsylvania, proposes that any person who served as a member of the army nurse corps or of the navy nurse corps during the World War and continuously thereafter until May 13, 1926, and who was, prior to June 20, 1930, separated from the corps by reason of physical disability incurred in line of duty, shall, on her application therefor, be entitled to be placed on the retired list of the Nurse Corps. H. R. 8615, introduced by Representative Marcantonio, New York, proposes that the Works Progress Administration shall immediately employ not less than 3,000,000 persons and that there be created a Federal Unemployment Assistance Administration to distribute grants of unemployment assistance to the various states that have set up a state relief plan in compliance with the standards approved by the Unemployment Assistance Administration. Among other things, the bill provides, relief plans must provide medical or surgical treatment or care by physicians or institutions of the relief recipient's choice, subject to a schedule of uniform fees as determined by the local relief administration. H. R. 8631, introduced by Representative South, Texas, proposes a federal appropriation of \$450,000 to construct a domiciliary unit at the veterans' facility at Legion, Texas, of sufficient capacity to accommodate 400 veterans.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 3425, introduced by Senator King, Utah, and H. R. 8587, introduced by Representative Kennedy, Maryland, propose to provide for the reorganization of the Government of the District of Columbia. Among other things, these bills provide that in selecting a health officer the Commissioners of the District of Columbia may request the President of the United States to designate an officer from among the medical officers in the United States Army Medical Corps, the United States Navy Medical Corps or the United States Public Health Service, and that the President, in his discretion, may designate such an officer who shall, during the time specified by the President, be health officer of the District. These bills also propose to abolish the office of coroner and to establish the office of medical examiner to function under the direction of a chief medical examiner appointed by the Commissioners of the District and who must be "a doctor of medicine and a skilled pathologist

with not less than two years' actual experience as a pathologist." A new License Department, it is proposed, will be created in which will devolve the duties heretofore exercised by various boards, departments, offices and commissions, including the Commission on Licensure to Practice the Healing Arts. The Commissioners of the District will be authorized to appoint licensing and examining boards.

STATE MEDICAL LEGISLATION

Kentucky

Bills Introduced.—H. 403 proposes that no physician, chiropractor, osteopath, chiroprapist, dentist or pharmacist shall practice his occupation or profession until he has first paid \$6 and obtained a license from the county court clerk of the county wherein he proposes to practice. H. 446 proposes to enact a law regulating the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and therapeutic devices "which shall be uniform in principle with the Federal Food, Drug and Cosmetic Act of 1938 and with the Federal Trade Commission Act, to the extent to which it outlaws the false advertising of food, drugs, devices and cosmetics." S. 199 and H. 438 propose to regulate the construction and operation of hospitals, both private and governmental, and clinics and require them to be licensed annually by the state board of health.

Bill Passed.—H. 340 passed the house and senate to amend the law prohibiting the issuance of a license to marry unless each party to the proposed marriage presents a physician's certificate as to freedom from venereal disease by proposing that the physician's certificate must state that the party is free from any stage of syphilis infection which is or is likely to become communicable.

Mississippi

Bills Introduced.—H. 381 proposes to prohibit the retail sale or distribution of contraceptive devices or any prophylactic rubber or skin goods for the prevention of venereal diseases except by a licensed physician or a licensed pharmacist. H. 387 proposes to create a charity hospital to be known as the North Mississippi Charity Hospital and to be of sufficient size properly to care for 150 patients or more. H. 261 proposes that more than 0.15 per cent of alcoholic content in the blood shall be prima facie evidence of intoxication.

Bill Passed.—H. 150 passed the house, February 21, proposing to prohibit the retail sale or distribution of barbituric acid and any compound, manufacture, salt, derivative, mixture or preparation of barbituric acid, except on the written prescription of a licensed physician, dentist or veterinarian. The bill further proposes to make it unlawful for any person to have in his possession or custody any drug or medicine containing any quantity of barbituric acid, unless it has been prescribed by a physician, dentist or veterinarian.

New York

Bills Introduced.—S. 1100 and A. 1339 propose to provide a public expense for the correction by surgical or medical treatment and care, or by hospitalization, of remedial physical defects or remedial physical disability of physically handicapped adults or unemployed persons in such manner as reasonably may be expected to fit them for remunerative occupations or employment. A. 1477, to supplement the workmen's compensation act, proposes that every employee mentally disabled as a result of an accident arising out of and in the course of his employment shall be entitled to receive, without any deductions from the amount of compensation payable to him, medical care, maintenance and attendance in a public hospital or institution, at the expense of his employer, until such time as the employee is discharged as cured. S. 1220 proposes to permit the sale of hypodermic syringes and hypodermic needles to podiatrists, without the written order of a duly licensed physician or veterinarian.

Rhode Island

Bill Introduced.—S. 131 proposes to grant to physicians treating persons injured by reason of an accident not covered by the workmen's compensation act liens on all rights of action, judgments, settlements or compromises accruing to the injured persons by reason of their injuries.

Virginia

Bills Introduced.—S. 253 proposes to authorize the operation of such nonprofit hospital and medical service plans as may be

approved by the state corporation commission. H. 338 proposes to appropriate annually to the state board of health \$1,000 for the purchase and distribution without charge of insulin to licensed physicians treating indigent patients suffering from diabetes mellitus. S. 186 proposes that whenever in a civil or criminal proceeding issues arise on what the court deems expert evidence desirable the court may, on its own motion or on the motion of either party to the proceeding, appoint one or more experts, not exceeding three on each issue, to testify at the trial.

OFFICIAL NOTES

THE NEW YORK SESSION

Hotels in New York

On advertising page 41 of this issue of THE JOURNAL is printed a list of New York hotels and rates for rooms that has been furnished by the Subcommittee on Hotels of the Local Committee on Arrangements.

The form printed in the advertising pages may be clipped and, when it has been properly filled in, should be sent at once to Dr. Peter Irving, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, Room 1036, 233 Broadway, New York.

Meeting Places

Meeting places at the annual session of the American Medical Association, to be held in New York June 10 to 14, will be as follows:

HOUSE OF DELEGATES: The Waldorf-Astoria, Basildon and Jade rooms.

GENERAL SCIENTIFIC MEETINGS: The Waldorf-Astoria, Ballroom, and the Commodore, Grand Ballroom.

REGISTRATION AND SCIENTIFIC AND TECHNICAL EXHIBITS: Grand Central Palace.

SYMPOSIUM ON HEALTH EDUCATION: Hotel Roosevelt, Grand Ballroom.

WOMAN'S AUXILIARY: Hotel Pennsylvania.

SECTIONS OF THE SCIENTIFIC ASSEMBLY

PRACTICE OF MEDICINE: The Waldorf-Astoria, Ballroom.

SURGERY, GENERAL AND ABDOMINAL: The Commodore, Grand Ballroom.

OBSTETRICS AND GYNECOLOGY: The Commodore, Grand Ballroom.

OPHTHALMOLOGY: Hotel Roosevelt, Grand Ballroom.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY: Hotel Roosevelt, Grand Ballroom.

PEDIATRICS: The Waldorf-Astoria, Ballroom.

PHARMACOLOGY AND THERAPEUTICS: The Biltmore, Music Room.

PATHOLOGY AND PHYSIOLOGY: The Biltmore, Music Room.

NERVOUS AND MENTAL DISEASES: The Biltmore, Ballroom.

DERMATOLOGY AND SYPHILOLOGY: The Commodore, West Ballroom.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH: Hotel Roosevelt, Hendrik Hudson Room.

UROLOGY: The Commodore, West Ballroom.

ORTHOPEDIC SURGERY: The Biltmore, Ballroom.

GASTRO-ENTEROLOGY AND PROCTOLOGY: Hotel Roosevelt, Hendrik Hudson Room.

RADIOLOGY: The Commodore, East Ballroom.

MISCELLANEOUS TOPICS, SESSION ON ANESTHESIA: The Commodore, East Ballroom.

ADDRESSES BY OFFICIAL STAFF

DR. PAUL C. BARTON:

March 19—Open meeting under auspices of St. Joseph Clinical Society, St. Joseph, Mo.

March 20—St. Joseph Clinical Society.

March 20—Woman's Auxiliary to Buchanan County Medical Society, St. Joseph, Mo.

DR. W. W. BAUER:

March 4-5—General Advisory Committee on Maternal and Child Welfare Services, Children's Bureau, Washington, D. C.

March 10—Kollege Klub, Evanston, Ill.

March 11—Automotive Boosters Club No. 7, Chicago.

March 12—Bryn Mawr Parent Teacher Association, Chicago.

March 26—Allegheny County Medical Society Auxiliary, Pittsburgh.

April 1—Woman's Club, Stevens Point, Wis.

April 1—Rotary Club, Stevens Point, Wis.

April 1—High School, Stevens Point, Wis.

April 2—Portage County Medical Society and Auxiliary, Stevens Point, Wis.

April 2—Teacher's College, Stevens Point, Wis.

April 2—Kiwanis Club, Stevens Point, Wis.

April 3—Wilmette Woman's Club, Wilmette, Ill.

DR. MORRIS FISHBEIN:

March 3—Bloomington Forum, Bloomington, Ill.

March 5—Fort Smith Junior College, Fort Smith, Ark.

March 10—South Parkway Branch of the Y. W. C. A., Chicago.

March 11—Uniontown Community Forum, Uniontown, Pa.

March 14—Illinois State Medical Society, Danville, Ill.

March 20—Temple Isaiah Israel, Chicago.

March 26—Executives Club, Knoxville, Tenn.

March 27—Executives Club, Chattanooga, Tenn.

March 31—Academy of Medicine, Rochester, N. Y.

DR. R. G. LELAND:

March 2—Professional Students Clinic, Y. M. C. A., Chicago.

DR. PAUL A. TESCHNER:

March 4—North End Woman's Club, Chicago.

March 6—Marinette County Medical Society Auxiliary and Woman's Club, Marinette, Wis.

DR. NATHAN B. VAN ETEN:

March 2—Dinner to Dr. Emily Barringer by Kingston Hospital at New York Academy of Medicine, New York.

March 6—Lecture on Ethics, New York University School of Medicine, New York.

March 9—Dinner Class of 1890, Bellevue Hospital Medical College, New York.

March 11—New York Society of Medical Jurisprudence, New York.

March 13—Lecture on Ethics, New York University School of Medicine, New York.

March 14—West Side Clinical Society, New York.

March 19—American Dental Association, Baltimore.

March 25—Radio Broadcast, New York University, New York.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Roy J. Settle, formerly of Inman, S. C., has been elected health officer of Clarke County, succeeding Dr. Benjamin S. Black, Grove Hill, who resigned to enter private practice in Chicago.—Dr. John A. Kenney, formerly medical director of the Community Hospital, Newark, N. J., has been appointed to a similar position at the John A. Andrew Memorial Hospital, Tuskegee Institute.—Franklin A. Clark, of the U. S. Public Health Service, has been appointed director of the division of inspection of the state department of health, succeeding C. A. Abele, Ch.E., who left to become director of the division of dairy products of the Chicago Board of Health, newspapers reported, January 18.—Dr. William M. Askew Jr., formerly of Auburn, has been named health officer of Butler County, succeeding Dr. Thomas C. Elliott, Greenville, resigned.

CALIFORNIA

Course in Psychotherapy.—Announcement is made that the course on psychotherapy in general practice at Mount Zion Hospital, San Francisco, will be given March 7, 14, 21 and 28 instead of March 6, 13, 20 and 27 as heretofore announced. Additional information may be obtained from Dr. Jacob Kasanin, chief of the psychiatry service at the hospital, corner of Post and Scott streets, San Francisco.

Director of Child Guidance Clinic.—Dr. Hale F. Shirley, assistant professor of psychiatry, State University of Iowa College of Medicine, Iowa City, has been appointed assistant professor of psychiatry and pediatrics and director of the new child guidance clinic at Stanford University School of Medicine. The Commonwealth Fund recently gave a grant of \$10,000 a year for three years to finance the clinic under the direction of the departments of psychiatry and pediatrics. The new clinic will be an expansion of the present work on behavior problems and will provide opportunities for graduate and undergraduate training of physicians in this field. Dr. Shirley graduated at the State University of Iowa College of Medicine in 1927.

Society News.—Dr. Charles E. Smith, San Francisco, addressed the Kern County Medical Society in Bakersfield, January 18, on "Coccidioid Granuloma in Relation to Erythema Nodosum."—At a meeting of the Riverside County Medical Association in Riverside, January 8, Dr. Robert W. Lamson, Los Angeles, spoke on "Allergy in General Practice."—Dr. Charles W. Barnett, San Francisco, discussed treatment of syphilis before the Yuba-Sutter Medical Society in Marysville, January 9.—At a meeting of the Los Angeles Society of Ophthalmology, February 26, the speakers included Drs. Helen L. Hopkins on "Hysterical Amblyopia in Children" and Harry F. Dietrich, "Arterial Hypertension in Children."—The Los Angeles Heart Association was addressed, February 14, among others, by Drs. Robert W. Langley on "Mediastinal Tumor Associated with Auricular Fibrillation" and Edward W. Boland, "Oxygen for the Relief of Pain in Coronary Thrombosis."

CONNECTICUT

Dr. Bayne-Jones Declines Reappointment as Dean.—Dr. Stanhope Bayne-Jones, since 1935 dean of Yale University School of Medicine, New Haven, has found it impossible to accept reappointment to this position, it is announced. His time will be devoted to other positions as chairman of the executive committee of the division of medicine and public health of the president's committee on university development, as director of the board of scientific advisers of the Jane Coffin Childs Memorial Fund for Medical Research and as professor of bacteriology. Dr. Bayne-Jones was chosen unanimously for reappointment by his colleagues on the board of permanent officers of the medical school, by the president and by the corporation of the university. He graduated at Yale in 1910 and from Johns Hopkins University School of Medicine in 1914. He joined the Yale faculty in 1932. He has served as professor of bacteriology, University of Rochester School of Medicine, Rochester, N. Y., and director of the Rochester Health Bureau Laboratories, among other activities. He was

chairman of the division of medical sciences, National Research Council, 1932-1933; member of the Council on Pharmacy and Chemistry of the American Medical Association, 1930-1934, president of the Society of American Bacteriologists, 1929-1930, and of the American Association of Immunologists, 1930-1931.

DISTRICT OF COLUMBIA

Life Membership in District Society.—Eight members of the Medical Society of the District of Columbia were recently elevated to life membership. The eight physicians are Drs. Thomas Dowling, Wilmington, Del.; Thomas A. Groover, Robert S. Lamb, Carl S. Keyser, Frederick H. Morhart, Charles S. White, Harry Hurtt and Henry A. Polkinhorn. To receive this honor it is necessary to be an active member of the society for forty years.

Society News.—The Medical Society of the District of Columbia was addressed, February 28, by Drs. George W. Thorn, Baltimore, on "Clinical Considerations Regarding the Use of Desoxycorticosterone Acetate Therapy in Addison's Disease" and Alva D. Daughton, "Simmond's Disease: Presentation of a Proved Case with Consideration of a Differential Diagnosis." The section on gastro-enterology presented a symposium and panel discussion on peptic ulcer before the society, February 14; the speakers were Drs. Ernest H. Gaither, Baltimore, on "Comparative Analysis of the Results of Various Forms of Medical Management of Peptic Ulcer" and George P. Müller, Philadelphia, "End Results and the Surgical Approach to Peptic Ulcer."—Dr. Francis C. Wood, Philadelphia, discussed "Coronary Diseases" before the naval medical and dental officers on duty in the District of Columbia and vicinity at the U. S. Naval Medical School, Washington, February 5.

ILLINOIS

Postgraduate Conference.—The third of a series of postgraduate conferences sponsored by the Illinois State Medical Society will be held at DuQuoin, March 7. Dr. Gilbert H. Edwards, Pinckneyville, president of the Perry County Medical Society, will preside. The speakers will include:

Dr. Andy Hall Jr., St. Louis, Urinary Tract Infections.
Dr. Clinton W. Lane, St. Louis, Diagnosis and Treatment of the Common Skin Diseases.
Dr. Joseph C. Jaudon, St. Louis, Problems of the Newborn.
Dr. Robert S. Berghoff, Chicago, heart clinic (four patients).
Dr. Frederick H. Falls, Chicago, Management of Abortion.
Dr. Francis J. Dean Sauer, St. Louis, Hand Infections, Diagnosis and Treatment.
Dr. Philip H. Kreuscher, Chicago, Fracture Problems.
Dr. Charles W. Mayo, Rochester, Minn., Preoperative and Postoperative Care of the Surgical Case.
Dr. James H. Hutton, Chicago, Diagnosis of Endocrine Disorders.
Dr. Edwin S. Hamilton, Kankakee, Voluntary Health Insurance in Illinois.

Chicago

Public Meeting on Cancer.—Plummer Memorial Lecture.—The Henry Schmitz Memorial Lecture will be delivered by Dr. Francis Carter Wood at a public meeting, March 6, sponsored by the cancer research committee of the Chicago Woman's Club and the Chicago Medical Society. Dr. Wood will discuss cancer. The meeting will be held at the woman's club following an all day clinical session. At 6:30 the Chicago Medical Society will hold a reception and dinner in honor of Dr. Wood, who is director of the Institute of Cancer Research at Columbia University College of Physicians and Surgeons, New York. Dr. James Randolph Webster, clinical instructor in dermatology, Rush Medical College, will deliver the Mary Redfield Plummer Memorial Lecture, March 7, at the woman's club on "Primary Cancer of the Skin."

Selection of Pioneer Physicians.—In an address at the Rosenwald Museum of Science and Industry, January 9, Dr. William Allen Pusey, Chicago, a former President of the American Medical Association, gave his choice of the chief leaders of Chicago's early medical history. They include:

Daniel Brainard, 1835 to 1866.
John Evans, 1843 to 1858.
Nathan S. Davis, 1849 to 1904.
John H. Rauch, 1857 to 1894.
Christian Fenger, 1878 to 1902.
Frank Billings, 1881 to 1932.
Ludvig Hektoen, 1887 to the present.

The lecture, entitled "High Lights in the History of Chicago Medicine" was presented under the auspices of the Chicago Historical Society, the Society of Medical History of Chicago and the Institute of Medicine of Chicago. Following the lecture a reception was held in honor of Dr. and Mrs. Pusey and a tour made to see the medical exhibits at the museum which are being transferred into new quarters.

MEDICAL NEWS

811

Branch Meetings.—The Evanston Branch of the Chicago Medical Society was addressed by Dr. Burton C. Corbus Jr., February 1, on "Clinical Evaluation of Testosterone Propionate"; Drs. Richard H. Young and Robert P. Gilbert, "Use of Aminophylline for Control of Bronchial Spasm," and Dr. Seth E. Brown, "Use of a Hospital Blood Bank." A symposium on peripheral vascular disease was presented before the North Shore Branch, February 6, by Drs. Louis G. Herrmann, Cincinnati, Frank V. Theis and Samuel Perlow. The branch will be addressed, March 5, by Drs. Russell L. Hayden, Cleveland, on "Some Aspects of Polycythemia of General Interest," and Charles A. Doan, Columbus, "The Reticulo-Endothelial System." The North Side Branch was addressed, February 1, by Drs. Ray F. Farquharson, Toronto, on "Hypopituitarism with Special Reference to Simmond's Disease," and Edward H. Ryncarson, Rochester, Minn., "A Skeptic Looks at Endocrinology." Dr. C. Sidney Burwell, Boston, will address this branch on "The Effect of Pregnancy on the Management of Heart Disease." Dr. W. Wayne Babcock, Philadelphia, will discuss "Diagnosis and Management of Inflammatory and Neoplastic Growths of the Colon" before the Englewood Branch, March 5.

LOUISIANA

Personal.—Dr. John H. Musser, New Orleans, received the Alumni Award of Merit of the University of Pennsylvania School of Medicine, Philadelphia, on Founder's Day, January 17, as part of the observance of the bicentennial of the university. Dr. Musser graduated in 1908.

Society News.—A symposium on pneumonia was presented before the Orleans Parish Medical Society, January 22, by Drs. Andrew V. Friedrichs, Stanford Chaille Jamison, Meyer D. Teitelbaum and Joseph O. Weilbaecher Jr.—Dr. Daniel N. Silverman, New Orleans, addressed the East Baton Rouge Medical Society recently on "Carcinoma of the Stomach."—A symposium on cutaneous diseases was presented before the Jefferson Davis Parish Medical Society at Jennings recently by Drs. James K. Howles, James W. Tedder and Charles Barrett Kennedy.

District Meetings.—The Fifth District Medical Society was addressed in Monroe recently among others by Drs. John Elliott, New Orleans, on "Memoirs of Forty-Five Years' Practice of Internal Medicine"; Edward N. Cook, Rochester, Minn., "Transurethral Prostatic Resection," and Henry Ashton Thomas, New Orleans, "Rhinitis and Otologic Problems of the General Practitioner."—At a meeting of the Third District Medical Society in New Iberia recently the speakers included Drs. Charles S. Holbrook and Leon J. Menville, New Orleans, on "Differentiating Depressive Reactions from Somatic Diseases" and "Present Day Methods of Diagnosing Tumors of the Breast" respectively.

MASSACHUSETTS

Society News.—The Boston Tuberculosis Association, the Southern Middlesex Health Association and the Trudeau Society of Boston held a joint meeting in Boston, January 25; following the business meetings of the tuberculosis and health associations Dr. Edward G. Huber spoke on "Tuberculosis as a Future Public Health Problem." In the evening Dr. Charles L. Jackson, Philadelphia, addressed the Trudeau Society of Boston on "Bronchoscopy in the Diagnosis and Treatment of Thoracic Disease."—Among others, Drs. John P. Hubbard and Robert E. Gross, Boston, addressed the Suffolk District Medical Society, January 31, on "Criteria for Ligation of the Patent Ductus Arteriosus in the Light of the First One and a Half Years' Experience."—Dr. Harry Linenthal, Boston, addressed the New England Heart Association, January 29, among others, on "Clinical and Pharmacologic Observations in Paroxysmal Ventricular Tachycardia."—The New England Society of Physical Medicine was addressed, January 4, by Mr. A. Philip Mooradian, New York, on "Comparative Physics of Long-Wave and Short-Wave Diathermy Generators."

MICHIGAN

The Henry Russel Lectureship.—Dr. Frank N. Wilson, professor of internal medicine, University of Michigan Medical School, Ann Arbor, was awarded the Henry Russel Lectureship in December. The lectureship is considered the highest university award and was established by the late Henry Russel, Detroit, a member of the class of 1873. Dr. Wilson will deliver the lecture at the university on May 2. The tentative title of his lecture is "The Electrical Currents Produced by the Human Heart."

Personal.—Dr. Roy H. Holmes, Muskegon, was elected editor of the state medical journal at a meeting of the council of the Michigan State Medical Society in January. He succeeds Dr. James H. Dempster, who resigned in December after serving in the position for twelve years. Dr. Dempster was presented recently with a scroll in recognition of his long service to the society.—Dr. Richard H. Lyons, Ann Arbor, has been appointed medical director of the Dr. William J. Seymour Hospital, the medical unit of Eloise Hospital and Infirmary, Eloise.

New Ophthalmologic Society.—The Detroit Ophthalmologic Society was organized at a meeting in the headquarters of the Wayne County Medical Society, Detroit, January 30. There will be five classes of membership: active, associate, honorary, life and special members. The officers elected are Drs. Parker Heath, professor of ophthalmology, Wayne University College of Medicine, president; Ralph H. Pino, president-elect; Leland F. Carter, secretary; Cecil W. Lepard, treasurer; Edmond L. Cooper, recorder. Honorary presidents are Drs. Don M. Campbell and Walter R. Parker. Dr. Campbell served as professor of ophthalmology at Wayne for more than forty years and Dr. Parker for twenty-eight at the University of Michigan Medical School, Ann Arbor.

MINNESOTA

Special Course in Pathology.—A course entitled "Surgical Pathology with Special Attention to Tumors" will be offered at the University of Minnesota Medical School, June 19-July 26. It is the same course presented by the university last summer by Dr. James S. McCartney, associate professor of pathology.

Society News.—The Hennepin County Medical Society was addressed in Minneapolis, February 21, by Drs. Joseph Michael and Nathaniel J. Berkwitz on "Pharmacologic Shock Therapy," and "Faradic Shock Treatment in Functional Psychoses," respectively.—Dr. Sumner L. S. Koch, Chicago, addressed the eighteenth annual dinner of the Minneapolis Surgical Society in Minneapolis, February 1, on "Transplantation of Skin and Subcutaneous Tissue to the Hand." Dr. Koch was presented with a certificate of honorary membership following his lecture.—Dr. Carl J. Wiggers, professor of physiology, Western Reserve University School of Medicine, Cleveland, gave a Mayo Foundation lecture, February 8, on "Ventricular Fibrillation."

MISSISSIPPI

Regional Meeting on Pediatrics.—The annual meeting of region II of the American Academy of Pediatrics will be held at the Edgewater Gulf Hotel, Edgewater Park, March 15-16. Region II of the academy comprises the southern states from Virginia to Texas.

Birmingham Physicians Give Program.—The following program was presented by Birmingham physicians before the Central Medical Society of Mississippi at Jackson recently: Dr. Ellis Dice Lineberry, A Consideration of the Individual Along with His Disease—Three Case Reports. Dr. Thomas M. McLester, The Commoner Forms of Nutritive Deficiency. Dr. Paul W. Shannon, Hydatidiform Mole. Dr. Wallace A. Clyde, Compound Fractures. Dr. Menigitis. Dr. Louis C. Posey, Pathology of the Endometrium. Dr. John L. Carmichael, Breast Tumors.

NEBRASKA

Personal.—Dr. Arthur C. Stokes has retired after more than thirty years as medical director of the Guarantee Mutual Life Insurance Company of Omaha. Dr. James P. Donelan, formerly of Los Angeles, is his successor.—Drs. Joseph E. Dunn and Frank A. Burnham, Arnold, were honored at a public meeting on January 18. The two physicians were presented with quilts on which were embroidered the names of several hundred persons at whose births they had officiated.

Society News.—Drs. Herschel B. Morton and E. Burkett Reed, Lincoln, addressed the Madison Six County Medical Society in Norfolk, January 16, on "Diagnosis and Treatment of Intestinal Obstruction: with Special Emphasis on the Miller Abbott Tube" and "Iron Deficiency Anemias" respectively.—Speakers at a meeting of the Fifth Council District in Columbus, January 9, were Drs. Arthur L. Miller, Kimball, president of the Nebraska State Medical Association, "The Physician's Public Relationship"; Wayne M. Hull, Oklahoma City, "Inhalation Therapy," and Frederick W. Niehaus, Omaha, "Rheumatic Heart Disease."

NEW YORK

Society News.—Dr. David Wolin, Rochester, addressed the Rochester Pathological Society, January 9, on "Clinical Aspects of Blood Diseases in Children."—The Medical Society of the County of Monroe, the Rochester Academy of Medicine and the University of Rochester School of Medicine sponsored a public meeting, January 28, with John R. Murlin, Ph.D., professor of physiology at the university, as the speaker on "The Place of Vitamins in Normal Nutrition."—Drs. Daniel B. Peeler and John A. Lichty Jr., addressed the Rochester Pediatric Society, January 12, on "Hypoglycemia" and "Recent Studies of Nephritis" respectively.

New York City

Science Writer Honored.—William L. Laurence, science news reporter of the New York Times, received the 1940 fellowship of the American Institute of the City of New York at a dinner at the Hotel Pierre February 1. Mr. Laurence was presented for the award by Oscar Riddle, Ph.D., of the research staff of the Carnegie Institution for Experimental Evolution, Cold Spring Harbor, L. I. His citation was "for a long-sustained pre-eminent record of reporting brilliantly to the daily press the achievements of science and technology."

Meeting on Tuberculosis and Heart Disease.—The thirty-eighth annual meeting of the New York Tuberculosis and Health Association, including the Tuberculosis Sanatorium Conference of New York and the New York Heart Association, will be held at the Hotel Pennsylvania March 5. Among the speakers will be:

Drs. James Burns Amberson Jr. and Carl Muschenheim, Detecting and Controlling Tuberculosis Among Hospital Personnel.

Dr. Herbert R. Edwards and Mr. Matthew Woll, third vice president, American Federation of Labor, The Labor Unions in Tuberculosis Control.

Dr. Henry D. Chadwick, Boston, The Tuberculosis Program in These Changing Times.

Dr. Homer F. Swift, Public Health Aspects of Rheumatic Disease.

A symposium on rheumatic fever will be presented by Drs. Thomas Duckett Jones, Boston; John R. Paul, New Haven, Conn., and Miss Edith Terry of the Massachusetts General Hospital, Boston.

Society News.—Dr. Harold G. Wolff will give the Friday afternoon lecture at the New York Academy of Medicine, March 8, on "Medical Treatment of Pain" instead of Dr. Walter L. Niles, as originally announced.—Drs. Terry M. Townsend, president of the Medical Society of the State of New York, and Richard B. Cattell, Boston, addressed the Medical Society of the County of Kings, Brooklyn, February 20, on "Who Shall Lead the Leaders?" and "Surgical Management of Diseases of the Biliary Tract," respectively. This society is presenting courses in contemporary medicine on Monday afternoons from March 4 to May 13. Subjects are allergy, tuberculosis, nontuberculous pulmonary disease, hematology, metabolism and nutrition.—Drs. Harry S. Gradle, Chicago, and Alfred Cowan, Philadelphia, addressed the Brooklyn Ophthalmological Society, February 15, on "Glaucoma Capsulare" and "Correction of Refractive Errors in Children" respectively.—Dr. Herbert S. Gasser was elected president of the Harvey Society at the annual meeting, January 26; Homer W. Smith, Sc.D., vice president, and Dr. Thomas Francis Jr., secretary, reelected.—Dr. Jacob M. Gershberg was recently reelected president of the International Spanish-Speaking Association of Physicians, Dentists and Pharmacists and Dr. James W. Babcock II, secretary.—Drs. George C. Adie, New Rochelle, and Cameron Haight, Ann Arbor, Mich., addressed the New York Society for Thoracic Surgery, February 9, on "Observations on Thoracoplasty for Treatment of Pulmonary Tuberculosis" and "Extrapleural Pneumothorax" respectively.—At a meeting of the American Society of Anesthetists, February 14, the speakers were Dr. Ralph M. Waters, Madison, Wis., on "Pain Relief in Obstetrics" and Detlev W. Bronk, Ph.D., Philadelphia, "The Influence of Anesthetics on the Activity of Nerve Cells."

OREGON

Society News.—Dr. Donald M. Long, Marshfield, addressed the Coos-Curry Counties Medical Society, Marshfield, January 10, on "Perforated Gastric Ulcers."—Drs. Moses E. Steinberg and Isidor C. Brill addressed the Multnomah County Medical Society, Portland, February 7, on "Problems in Gastric Surgery" and "Circulatory Failure with Special Reference to Digitalis" respectively.

Spring Course in Ophthalmology and Otolaryngology.—Drs. Meyer Wiener, professor of clinical ophthalmology, Washington University School of Medicine, St. Louis, and Marvin F. Jones, formerly professor of otolaryngology, New York Post-Graduate Medical School, will be the guest speakers at the fifth annual spring postgraduate course of the Oregon Academy of Ophthalmology and Otolaryngology. The course will be given in cooperation with the University of Oregon Medical School in Portland, April 1-6.

PENNSYLVANIA

Hospital Changes.—Dr. Thomas I. Cotton has resigned as superintendent of Selinsgrove State Colony for Epileptics, Selinsgrove. Dr. Ronald B. McIntosh, formerly on the staff of Norristown State Hospital, Norristown, is his successor.

Search for Meningitis Carriers.—Seven carriers of the organism of spinal meningitis have been found in and near Wilkes-Barre in Luzerne County, where forty-seven deaths from the disease have occurred since last September, according to newspaper reports. Plans were being made to examine 2,500 employees of a coal company in the area after it appeared that most of the cases occurred in families associated with mining.

Society News.—Dr. John P. Henry, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, February 8, on "Diseases of the Peripheral Arteries and Veins."—Dr. Michael Fresoli and Harry A. Rothrock Jr., Bethlehem, addressed the Northampton County Medical Society, February 16, at the Northampton Country Club on "Present Day Treatment of Pneumonia" and "The Laboratory in Pneumonia" respectively.—Dr. Barton R. Young, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, February 13, on "Roentgenology and the General Practitioner."—Dr. Joseph M. Shelton, Washington, addressed the Washington County Medical Society, Washington, February 14, on common diseases of the skin.

Philadelphia

Temple Alumni Meeting.—The Midwinter Alumni Day of the Medical Alumni Association of Temple University was held, February 29, with a program at the university hospital and the medical school during the day and dinner at the Hotel Warwick in the evening. Dr. Frank H. Lahey, Boston, was the guest speaker, presenting addresses on "Management of Thyroid Disease" and "Some of the Newer Developments in Surgery."

Joint Surgical Meeting.—The annual joint meeting of the New York Surgical Society and the Philadelphia Academy of Surgery was held in Philadelphia, February 14, with the following speakers: Drs. Eldridge L. Eliason and Julian Johnson on "Acute Regional Enteritis"; Hubley R. Owen, John Paul North and Lewis C. Manges Jr., "Fractures of the Shaft of the Humerus," and Thomas A. Shallow, "The Operative Technic of Pulsion Pharyngeal Diverticulum and Traction Diverticulum of the Esophagus." Drs. Richard H. Meade Jr., Joshua Montgomery Deaver, Gilson C. Engel and Hans May presented case reports.

Personal.—Dr. Thomas S. Dunning, aged 92, was honored by the Dickinson Club of Philadelphia, January 10, as the oldest living alumnus of Dickinson College. He was graduated in 1867.—Dr. John Claxton Gittings received the degree of bachelor of arts from the University of Pennsylvania, February 17, as a member of the class of 1894, by a special request of that class addressed to the president of the university. It was said that when Dr. Gittings was a sophomore he was compelled to drop out of the university because of his eyes. Instead of completing his academic work he went directly to medical school, graduating in 1895.

Lectures on Genetics.—The Woman's Medical College of Pennsylvania is presenting a series of lectures on "Medical Genetics," made possible by a gift from an alumna of the class of 1889. Charles B. Davenport, Ph.D., of the Carnegie Institution laboratory at Cold Spring Harbor, N. Y., delivered the first lecture, February 26, on "Human Variability and Mate Selection." Dr. Davenport will give the second, March 4, on "Some Social Applications in Eugenics." On March 11 there will be four speakers at an afternoon meeting:

Dr. Davenport, Heredity in Relation to Medicine.
Clyde E. Keeler, Sc.D., Boston, The Value of Animal Experiments in the Understanding of Human Genetics.
Maud Slye, Sc.D., Chicago, Genetics and Cancer.
Dr. Madge Thurlow Macklin, London, Ont., The Value of Medical Genetics to the Clinician.

Pittsburgh

Society News.—Speakers before the Allegheny County Medical Society, February 20, were Drs. James Everett McClenahan on "Intestinal Intubation; Its Application in Intestinal Obstructions"; Sidney A. Rosenberg, "Results in Reconstructive Surgery," and Daniel P. Greenlee, "Malignancy of the Gallbladder." Dr. Floyd H. Bragdon presented a motion picture on "Surgical Treatment of Paroxysmal Convulsive Disorders."—Drs. John Huber Wagner and Stuart N. Rowe addressed the Pittsburgh Surgical Society, February 6, on "Periarticular Adhesions of the Shoulder Joint with Treatment by Manipulation" and "Osteomyelitis" respectively.—Dr. Maud L. Menten, among others, addressed the Pittsburgh Pediatric Society, February 9, on "Childhood Anemias Associated with Erythroblastosis."—At a meeting of the Pittsburgh Urological Association, February 12, the speakers were Drs. Stacy M. Hankey, Pittsburgh, and Louis Bernstein, Aspinwall, on "Conservative Treatment of Hydronephrosis" and Clifford M. Lane on "Polycystic Disease of the Kidney."—Dr. Richard B. Cattell, Boston, gave the R. W. Stewart Memorial Lecture of the Pittsburgh Academy of Medicine, February 13, on "Carcinoma of the Rectum."

GENERAL

Grants for Research in Sex.—Applications to the National Research Council for funds to support study of fundamental problems of sex and reproduction should be received before April 1, according to a notice in *Science*. They may be addressed to the chairman of the committee for research in problems of sex, Robert M. Yerkes, Sc.D., Yale University School of Medicine, New Haven, Conn. Preference will be given to proposals for the investigation of neurologic, psychobiologic and behavior problems.

All Expense Tour to Federation Meeting.—Dr. Arno B. Luckhardt, professor of physiology, University of Chicago, is sponsoring an all expense tour for persons attending the annual meeting of the Federation of American Societies for Experimental Biology, New Orleans, March 13-16. The tour will leave Chicago Monday morning March 11 and arrive in New Orleans Tuesday morning March 12. Information may be obtained from Dr. Luckhardt, Department of Physiology, University of Chicago, Chicago.

Delegates to the Pharmacopeial Convention.—All medical schools and medical societies who expect to send delegates to the U. S. Pharmacopeial Convention to be held in Washington, D. C., May 14-16, should send the credentials to the board of trustees of the U. S. Pharmacopeia before March 15. If the blank forms have been misplaced, duplicate copies may be obtained by addressing E. Fullerton Cook, Philadelphia College of Pharmacy and Science, Philadelphia, chairman of the Revision Committee of the U. S. Pharmacopeia.

Impostor Victimizes Physicians.—The California State Board of Medical Examiners reports that an impostor has been victimizing professional and business men by fraudulent checks drawn on the Crawford County Trust Company, Meadville, Pa. He usually approaches his victims by announcing that he proposes to open an office as a physician specializing in surgery. The man is said to be about 38 years old and 5 feet 6 or 7 inches tall. He weighs from 135 to 140 pounds, has brown eyes, is partly bald and wears horn-rimmed glasses. He wears a small moustache and acts nervous, it is said. Names he has used are "Dr." Marven Gordon Dietz, "Dr." Morgen Brooks and "Dr." Morris.

Society News.—Dr. Paul R. Cannon, Chicago, was elected chairman of the section on medical sciences (N) and a vice president of the American Association for the Advancement of Science at the recent meeting in Columbus.—Dr. Arthur E. Strauss, St. Louis, was installed as grand consul of Phi Delta Epsilon medical fraternity at the annual meeting in New York, December 30, succeeding Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL. Dr. Israel S. Zinberg, Baltimore, was elected grand consul-elect; Dr. Leo H. Crip, Pittsburgh, vice consul, and Dr. Benjamin Edgar Spiegel, New York, grand scribe.—Dr. William W. Wasson, Denver, was named president-elect of the Radiological Society of North America at its annual meeting in Atlanta, Ga., in December. Dr. Bernard H. Nichols, Cleveland, was installed as president. Vice presidents elected were Drs. Robert R. Newell, San Francisco; Rabun T. Wilson, Austin, Texas, and Leo G. Rigler, Minneapolis. Dr. Donald S. Childs, Syracuse, was reelected secretary.—The Women's Field Army of the American Society for the Control of Cancer held its second national assembly in Louisville, Ky., February 14-16.—Dr. Ruth E. Boynton, Minneapolis, was elected president of the American

Student Health Association at its recent annual meeting in New York. Dr. Fred N. Miller, Eugene, Ore., was elected vice president and Dr. Ralph I. Canuteson, Lawrence, Kan., secretary.

The Sixteenth Decennial Census.—The Bureau of the Census announces that the sixteenth decennial population census of the United States will be conducted in April by 120,000 enumerators. A force of 7,000 statisticians and clerks under the supervision of the bureau's permanent staff will tabulate the figures, making the results available in a short time, it is expected. This year's census will include questions designed to provide illuminating data on problems that have become particularly pressing in the last decade. New statistical knowledge will be developed on education, mass migration, employment, unemployment, occupation and income. There are thirty-three questions on the general population schedule. Of these the average person will have to answer not more than half, according to the announcement. Twenty of these are general questions relating to location, household data (number in family and kind of home), name, relationships, personal description, education, place of birth, citizenship and place of residence five years ago. This last question is designed to measure internal migration, such as movements from the dust bowl areas. The last thirteen questions in the general list concern employment and will be addressed to all persons over 14 years of age. A special group of questions will be asked of one in every twenty persons enumerated to provide the Census Bureau with a statistical sample to fill requests for information on special subjects. These questions are on the following subjects: place of birth of mother and father, mother tongue, veterans of military service, social security status, usual occupation (this is designed to determine how many persons are working outside their usual occupations) and women who are or have been married. Separate censuses are being made of business, manufactures and mines and quarries. These have been under way since January. Concurrent with the population census in April will be the censuses of housing, agriculture and irrigation and drainage.

Red Cross to Enroll Medical Technologists.—At the request of the surgeon general of the U. S. Army and in compliance with its policy of cooperation with the army and navy, the American Red Cross has undertaken the enrolment of various types of medical technologists who are willing to serve in the medical department of the army and navy if and when their services are required at the time of a national emergency. Persons with the following qualifications will be enrolled:

Chemical laboratory technicians (male).
Dental hygienists (male and female).
Dental mechanics (male).
Dietitians (male and female).
Laboratory technicians (male and female).
Meat and dairy hygienists (inspectors) (male).
Nurses (male).
Occupational therapy aides (male and female).
Orthopedic mechanics (male).
Pharmacists (male and female).
Physical therapy technicians (aides) (male and female).
Statistical clerks (male and female).
X-ray technicians (male and female).

Male nurses will not be members of the army or navy nurse corps, which under basic laws are limited to women, but will be used as technologists for service auxiliary to the regular corps. Male technologists will be eligible for enlistment in the army as noncommissioned officers in the grades of sergeant, staff sergeant or technical sergeant. Women technologists and men who do not qualify physically will be eligible for employment by the army as civilians. For the navy, male technologists will be eligible for enlistment in the naval reserve as petty officers—pharmacist's mates third, second and first class and chief pharmacist's mate (acting appointment). Women are not eligible for service in the navy, according to present plans. General qualifications for enrolment are as follows: citizens of the United States; ages 21-45 for the army and 18 to 35 (men only) for the navy; physically qualified; women must be unmarried; all must express willingness to serve as technologists in time of a national emergency. The medical department of the army will require a considerable number of technologists in all groups; the navy's requirements will be similar except that dietitians, occupational therapy aides, orthopedic mechanics and dairy and food hygienists (inspectors) will not be needed. The navy also desires peace time enlistment in the U. S. Naval Reserve, and male technologists who wish to enlist are urged to communicate directly with the commandant of the naval district in which they live. Technologists who qualify for this service and are willing to enroll should communicate with the American National Red Cross, Washington, D. C.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Jan. 26, 1940.

Ambulances for Finland

The admiration and sympathy for the Finns in their heroic stand against aggression is manifested in a practical form. We are doing what we can while engaged in a struggle of the same kind. A voluntary ambulance unit of the Women's Transport Service for work with the Finnish Red Cross is being sent. It consists of ten ambulances presented by the Canadian Red Cross, the British Red Cross and the officers of the Women's Transport Service. They are modeled on the lines of the British War Office type on a 24 horsepower eight cylinder Ford chassis and are internally heated. There is antifreeze mixture in the radiators, and a special paraffin burner is carried under the bonnet. The unit was inspected by the princess Alice in the presence of the Finnish minister and other foreign ministers and by the high commissioners for Canada and other dominions. The Finnish minister said that they would be an encouragement to the Finns in their struggle against tremendous odds. Care has been taken to equip the women of the unit against the rigors of the Finnish winter. They are equipped with men's woolen underclothing, of which they will wear two sets at a time. A second pair of heavy wool socks will be worn over the ski trousers.

Increase of Road Accidents Due to the Black Out

An increase of road accidents due to the darkness of the black out has been previously described. The number of deaths from this cause in December was 1,155, the highest in any month since records have been kept and an increase of 212 over December 1938. The highest previous record for one month was in September, the first month of the war, when 1,130 persons were killed. In October the figure fell to 919 and in November it was 926. The December 1939 figure included 820 pedestrians, the great majority of whom were killed during the black out. On very dark nights it is not uncommon for seven cases of fracture due to the black out to be brought into one London hospital. During the whole of 1939 the road deaths totaled 8,270 as compared with 6,599 in 1938. Of last year's total 849 were pedestrians under 15 years of age; 3,644 were pedestrians over 15; 1,064 were motorcyclists and 1,374 were pedal cyclists.

The National Safety First Association in an appeal for greater care on the roads emphasizes that the road deaths are now increasing at the rate of nearly 5,000 a year. Unnecessary use of the road at night should be avoided. Pedestrians who must be out should remember that their invisibility makes the danger and should protect themselves by wearing or carrying something white or luminous. So far the first four months of the war has increased the road deaths by 1,639 (66 per cent).

Improvement in the Health of Children

Sir Arthur Salusbury MacNalty, chief medical officer to the Board of Education, in his annual report said that for more than thirty years the school medical service has been actively promoting the health and welfare of school children. While we are far from perfection, school children of today in general health, physique and stature are much better than they were at the beginning of this period. During the year the nutrition of 1,674,023 children was assessed in routine medical inspection. In 14.5 per cent it was excellent, in 74.2 per cent normal, in 10.8 per cent slightly subnormal and in only 0.5 per cent bad. In many cases the local school authorities supply free meals or milk. The number of children receiving either of these was 687,855 in 1938-1939. In March 1939 the milk in schools scheme

was in operation in 86.9 per cent of all the departments of public elementary schools. The schools not operating it were mainly small rural ones containing less than 5 per cent of the children; 55.6 per cent of the children were taking milk under the scheme either free or on payment. On the advice of Professor Drummond some necessitous children were fed by the Oslo method and compared with others fed on the usual hot two course dinners. The "Oslo meal" consisted of salad (lettuce or, in winter, raw cabbage), tomatoes, cucumber, salad dressing, 1½ ounces of cheese, 3 ounces of brown bread, one-fourth ounce of butter, two thirds of a pint of milk and a raw apple or orange. The vegetables were made into a salad, and grated cheese was served on top. The children so fed showed a considerable advantage compared with controls. Many had not eaten brown bread before. The meal takes at least half as long again to consume as the two course hot dinner, as there is so much hard food to masticate.

COPENHAGEN

(From a Special Correspondent)

Jan. 16, 1940.

Preparations for Blood Transfusion in Wartime

With war looming near, the central committee of the Danish Medical Association has urged the nation to rally to the Danish Red Cross to help it realize its scheme for blood typing. Danish doctors have undertaken to make no charge for the taking of samples of blood for type determinations, and men and women exempt from military duties and between the ages of 18 and 60 have been urged to report to the nearest branch of the Danish Red Cross for information concerning blood donation. The State Serum Institute in Copenhagen has undertaken the necessary type determinations, a tremendous task.

The response to the appeal for donors for a wartime emergency has been so generous that in a short time over 29,000 persons answered it, and nearly 27,000 have passed the necessary tests and have been registered both at the headquarters of the Danish Red Cross and with the local branches to which they belong. In one district, Lolland, a special study has been made of the relative numbers of the different blood types. It was found that 38.7 per cent belonged to type O, 47.3 per cent to type A, 9.8 per cent to type B and only 4.2 per cent to type AB. The Danish army medical service is well satisfied with this ample reserve of donors, who, it is understood, will not be called on to shed their blood in any but a wartime emergency. For the emergencies of peace other arrangements are already in force.

The headquarters of the Danish Red Cross has been urged to devise a system for keeping the registers, central and local, constantly down to date, with special reference to the changes of the addresses of donors. In a recent issue of the *Ugeskrift for læger*, Dr. Erik Brammer pointed out how advantageous it might be for the prospective recipients of transfused blood if the rule was made of typing the blood of all persons whose blood is examined for some other purpose. In the course of time much valuable information would be obtained with regard to not only the donors but also the recipients of transfused blood.

The Declining Syphilis Rate

The decline of syphilis in Denmark is so marked from year to year that one might be tempted to anticipate its complete extinction in our own time but for the import of new infections from abroad. In 1930 there were 1,678 notifications of new cases of acquired syphilis (as distinct from congenital syphilis) of which 116 new cases were notified in this year; in 1938 only 470 new cases of acquired syphilis were notified, the number of new cases of congenital syphilis notified being down to fifty in this year. Between 1930 and 1938 the ratio of new cases of acquired syphilis per 10,000 inhabitants has declined from 4.7 to 1.2. These most encouraging figures must, however,

be taken with due reserve. For it is often a ticklish matter to notify a case of venereal disease, and when one is in doubt it is easy to forget. It is therefore just as well that the efficacy of notification can be controlled from time to time by another system: the records of Wassermann reactions at the State Serum Institute, in which the Wassermann testing is centralized for the whole of Denmark. Dr. P. Krag and Dr. Marie Lindhardt have compared these two sources of information in a laborious study, which shows how defective the notifications of new cases of syphilis are likely to be, especially in a large city such as Copenhagen. Yet there can be no doubt as to the reality of the decline in the frequency of syphilis in the recent past.

Alcohol and Traffic Accidents

What most impresses the foreign visitor to Copenhagen is the prodigious number of its bicycles. In the busy hours of the day they are so thick on the pavement that crossing the street seems a physical impossibility. In 1937 Copenhagen could boast only 27,711 motorcars and only 6,752 motorcycles, whereas its bicycles number some 400,000. Little wonder therefore that bicycles and bicyclists figure prominently in traffic accidents. At the University Medico-Legal Institute, which is under Prof. Knud Sand, the calculation has recently been made that 45 per cent of all the deaths from traffic accidents between the ages of 11 and 60 in the period from 1926 to 1937 concerned bicyclists. The common assumption that in clashes between motorists and bicyclists the motorist is the aggressor is not always fair to him, and when attempts are made to apportion blame by means of blood and urine tests for alcohol, the testing ought to be extended to the bicyclist and even to the pedestrian involved in a fatal accident. This principle was put into force by the Copenhagen police between two and three years ago, the public hospitals being instructed to undertake alcohol tests of the blood and urine of all patients admitted for traffic accidents. Professor Sand and Dr. P. H. Andresen have found an alcoholic concentration of more than 0.1 per cent in the blood of 44 per cent of the 174 persons injured in traffic accidents during 1937 and up to August 1938. These persons were between the ages of 15 and 60. It does not say much for the sobriety of the average Dane in Copenhagen that almost every other person involved in some traffic accident has such a disconcertingly high concentration of alcohol in his blood.

SWITZERLAND

(From Our Regular Correspondent)

Dec. 26, 1939.

New School of Psychotherapy in Zurich

Under the direction of a board of trustees of psychiatrists and neurologists and at the suggestion of the Psychotherapeutic Commission of the Swiss Society of Psychiatry, a school of psychotherapy has been founded in Zurich. It means to give an opportunity for a thorough education especially to physicians and to induct practicing physicians into the scientific problems involved. The phenomena of psychoneurosis will be taught by means of lectures and practical demonstrations. The connection between the special problems of psychologic research and the verified facts of medicine and biology is to be maintained. The membership of the board consists, in part, of Dr. Binswanger, Dr. Forel, Prof. C. G. Jung and Dr. Hans W. Maier, professor of psychiatry, of Zurich.

Congress of Psychiatrists and Neurologists

The Swiss neurologic society and the society of Swiss psychiatrists held a joint meeting in Lugano under the presidency of Prof. John Stachelin, of Basel. The main subject of discussion was neuropathology and psychopathology of occupational poisoning on which Professors Flury, of Würzburg, Hans W. Maier, of Zurich, and H. Steck, of Lausanne, read papers. Dr. Lüthy, of Zurich, discussed peripheral nervous lesions in occupational poisoning.

Hereditary Feeble-mindedness in Switzerland

In Switzerland, as in other countries, the fertility of the normal population is surpassed by that of families with hereditary feeble-mindedness. Investigations in the city of Winterthur found that the families from which children came that attended special classes for backward pupils were larger than those of normal children (on the average 3.3) while the normal family groups had fallen to an average of 2.1 and 2.5, respectively. Dr. Brugger, school physician in Basel, genealogically examined the children of parents of 1,396 normal pupils and those of 427 hereditarily feeble-minded pupils and published his observations in a book on "Hereditary Diseases and Their Control." The investigation plainly shows that for several decades and at all economic levels, in Basel as well as elsewhere, on the average the families in which hereditary feeble-mindedness was found were larger than those of the normal group. This difference in fecundity, he said, must slowly but progressively lead to an increase of the feeble-minded unless the necessary eugenic control measures are promptly taken.

European Commission for Mental Hygiene

The European Commission for Mental Hygiene held its sixth meeting at the same time, and Switzerland, Belgium, Estonia, France, Germany, Great Britain, Italy, the Netherlands, Poland, Rumania, Sweden, Switzerland, Turkey and Yugoslavia were represented. The sessions were devoted to phases of the problem of mutual understanding.

Personals

Prof. Alfred Vogt, ophthalmologist in Zurich, celebrated his sixtieth birthday. The *Schweizerische medizinische Wochenschrift* honored him with a special dedication.

Prof. Eduard Glanzmann, director of the children's clinic of the University of Berne, was appointed to the professorship of pediatrics.

Prof. Max Askanazy, professor of pathologic anatomy at the University of Geneva, has reached the age limit and retired. His pupil Dr. Erwin Rutishauser was chosen as his successor.

Prof. Bruno Galli-Valerio, professor of hygiene and bacteriology at the University of Lausanne, retired after rounding out fifty years of teaching. Dr. Paul Hauduroy, director of the health department of Colombes, near Paris, was appointed as his successor.

Prof. W. Ruzicka, of Zurich, was awarded the Marcel Benoist prize for 1938 in recognition of his contributions in the field of the sex hormones and the polyterpenes.

Deaths

Dr. Oscar Bernhard, founder of heliotherapy in surgical conditions, died Nov. 16, 1939, in St. Moritz at the age of 78 years. He was a pioneer in the field of modern heliotherapy. He was highly esteemed at St. Moritz and had honorary degrees from the Universities of Berne and Frankfurt on the Main.

Dr. Alexander Tschirch, for many years professor of pharmacognosy and pharmaceutic chemistry at the University of Berne, died at the age of 84 years. Tschirch was born in Prussia and had established himself in Berne as early as 1890. Many of his contributions became well known, especially those on chlorophyll, resins and medicinal and useful plants. He was also the author of a large textbook on pharmacognosy.

Prof. Wilhelm von Speyr, for more than forty years (1890-1933) director of the asylum for mental diseases ("Waldau") in Berne and professor of psychiatry at the University of Berne, died at the age of 86 years. His main interest lay in the field of mental diseases caused by the use of alcohol. He was a firm believer in total abstinence.

Prof. Eugen Bleuler died in Zollikon, near Zurich, at the age of 83 years. His death closed a career rich in accomplishments. He became director of a large Swiss asylum when he was 29 years of age. Here he introduced a program of "work

therapy." He was one of the first leading psychiatrists to show an understanding of Freud's theories. In 1897 he was appointed director of the psychiatric clinic of the University of Zurich and for thirty years served in that capacity. His contributions were fundamental to the progress of psychiatry. His monograph on "Dementia Praecox," published in 1911, made him famous. His "Textbook on Psychiatry," published in 1918 and translated into different languages, gave fundamental expression to the psychologic trend in the study of this subject. In 1919 he published "Autistic-Undisciplined Medical Thinking and Its Cure," widely read and discussed also by others than psychiatrists and of great influence on medicine and psychiatric research. Bleuler had the genuine modesty of the really great scientist. He was an imposing, distinctive personality, a tireless worker and an excellent administrator and teacher.

Buenos Aires

(From Our Regular Correspondent)

Jan. 3, 1940.

The New Institute of Physical Research

In November 1939 the Instituto de investigaciones físicas aplicadas a la patología humana was dedicated in Buenos Aires. The new institute, of which Prof. M. Castex, professor of internal medicine, is the director, is closely connected with the Argentine Academy of Medicine. At the first meeting a series of lectures was given in Professor Castex's clinic by specially trained assistants. The subjects treated were the comparison of urobilinogen dosage by different methods, the spectrophotometric study of Ehrlich's diazo reaction, pleurophotography, allergic toxemia and a new respirator.

Conference on Alcoholism

The Liga Argentina contra el Alcoholismo recently held its second session on alcoholism, which lasted four days. It was well attended and engaged the interest of the country's physicians to a considerable degree. Prof. A. H. Roffo and Dr. Gonzalo Bosch, members of the faculty of medicine, presided. Dr. Pablo J. O. Wolff spoke on the dangers of the cocktail, Dr. Luis L. Boffi on the relations between tuberculosis and alcoholism, Dr. C. N. de Fischer on alcoholism and its effects on the child, Dr. M. T. F. de Guadino on alcoholism in women, Dr. A. R. Rossi on alcoholism as a social disease, Dr. D. Madanes on the legal bases for the fight against alcoholism and Dr. J. L. Pavia on the harmful effects of alcohol on visual acuity.

Combating Hydatidosis

The Asociación Médica Argentina in a recent joint meeting with the veterinary society discussed the national problem of hydatidosis. Francisco Rosenbusch, professor of veterinary parasitology, said that in some sections of Argentina more than 50 per cent of the live stock was infested with hydatid cysts and that the farmers of these areas had no conception of the dangers inherent in hydatidosis for human beings. Medical opinion emphasized the need of extensive educational publicity and of laws against hydatidosis. A national commission was organized in Argentina for combating hydatidosis. The necessity of such a fight is discernible from the facts disclosed by the veterinary José R. Serres that Argentina, Iceland, Australia, New Zealand and Uruguay are the principal countries afflicted with these parasites. The president of the republic of Uruguay in a recent message called attention to this problem. The Sociedad de Biología in Concepción, Chile, recently directed attention to the frequency of the disease in that city.

Commemoration of First Blood Transfusions with Sodium Citrate

Until 1914 blood transfusions were attended with many difficulties, since no method was known to prevent coagulation. The method perhaps mostly employed was that of Crile, consisting in

the establishment of a direct anastomosis of the arteries of the donor and the receiver. In November 1914, during the first months of the World War, Prof. Luis Agote discovered that sodium citrate would prevent blood coagulation. He recognized at once the practical significance of his discovery and on November 9 performed the first transfusions in the presence of numerous physicians. The first press item of the discovery appeared in the New York *Herald* of November 14 and a further item on the following day. On November 22 the department of the exterior of Argentina made known the new method with the technical details to the diplomatic representatives of the belligerent countries stationed in Buenos Aires; that is, of Belgium, France, Germany, Great Britain, Russia and Turkey, a humane discovery in inhumane days. Two commemorative meetings were held in Buenos Aires in honor of the discovery and its discoverer.

The Academy of Surgery in Buenos Aires

The Society of Surgeons passed a resolution on the occasion of its twenty-fifth anniversary to convert the society into an academy. Now, three years later, the change has been made. The new Academy of Surgeons had its first meeting at the end of November 1939 with Prof. Rodríguez Villegas in the chair and was formally organized on December 20. The regular members of the former society constitute the membership of the new academy.

Personals

In November 1939 Juan R. Goyena, professor of internal medicine in Buenos Aires, celebrated his twenty-fifth anniversary as a teacher. Commemorative exercises were held. Goyena's field is principally that of gastric and intestinal disorders. He was chairman of the society for gastro-enterology, co-founder of the international society of the same name in Brussels and president of the Asociación Médica Argentina.

Dr. Gregorio Aráoz Alfaro, for twenty-five years president of the Argentine League against Tuberculosis, has resigned. The league, founded in 1901, now maintains two dispensaries with branches and owns a large building and two preventorios for children in rural districts. A large sanatorium is in process of construction.

Deaths

Prof. Francisco Llobet, professor of surgery in Buenos Aires, died in retirement on Nov. 2, 1939. Prof. Bernardino Maraini, until recently professor of clinical urology in Buenos Aires, died November 10. Both were esteemed as clinicians.

Marriages

NORBORNE BERKELEY POWELL, Dallas, Texas, to Miss Elizabeth Mary Balas of McKeesport, Pa., Dec. 18, 1939.

GEORGE V. LAUNEY JR., Fort Worth, Texas, to Miss Harriet Louise Pitts of Alexandria, La., January 6.

HUB E. ISAACKS, Fort Worth, Texas, to Mrs. Irene Lee Tomlinson, of Houston, January 15.

WILLIAM L. COLE, Evansville, Ind., to Miss Barbara Louise Bagley, of St. Louis, Nov. 23, 1939.

GEORGE L. KRAFT, Chicago, to Miss Alleen Hoffland, of Soldiers Grove, Wis., February 7.

KENNETH I. SHIEK, Greenwood, Ind., to Miss Mary Thompson, of Indianapolis, Dec. 2, 1939.

TIM JOSEPH MANSON, Chattanooga, Tenn., to Miss Elizabeth Taylor at Knoxville in February.

JOSEPH H. BALTES to Miss Margaret I. Walsh, both of Fort Wayne, Ind., Nov. 23, 1939.

HERSCHEL C. CRAWFORD to Mrs. Nellie Lafayette Kelly, both of Atlanta, Ga., February 8.

JOHN B. OGILVIE to Miss Ann Bassett Jones, both of New York, February 2.

Deaths

DEATHS

817

- David Murray Cowie @ Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; professor of pediatrics and infectious diseases and chairman of the department at his alma mater since 1920, assistant professor of the theory and practice of medicine from 1896 to 1899, first assistant in internal medicine from 1899 to 1906, instructor of pediatrics, 1906-1907, clinical professor of pediatrics from 1907 to 1909, clinical professor of pediatrics and internal medicine from 1909 to 1919 and professor of pediatrics and internal medicine, 1919-1920; secretary of the University of Michigan Pediatrics and Infectious Disease Society; member of the American Pediatric Society; member of the American Society of Pediatrics, International League Against Epilepsy, American Society of Clinical Investigation (vice president 1920-1921) and the American Association of Pathologists and Bacteriologists; fellow of the American College of Physicians; medical director and owner of a hospital bearing his name; associate editor of the *American Journal of Diseases of Children* from 1912 to 1924; aged 67; died, January 27, of coronary thrombosis.
- George Shattuck Whiteside @ Pine Orchard, Conn.; Harvard Medical School, Boston, 1897; fellow of the American College of Surgeons; past president and secretary of the Port-land (Ore.) City and County Medical Society; assistant in anatomy at his alma mater from 1898 to 1904; instructor, and later assistant professor of surgery, University of Oregon Medical School, Portland, from 1904 to 1916; served during the World War; at one time surgeon to the Multnomah Hospital, Portland; on the staff of the Greenpoint Hospital, Brooklyn, from 1932 to 1938; aged 66; died, January 29, in New York, of heart disease.
- Webb William Weeks @ New York; Columbia University College of Physicians and Surgeons, New York, 1912; professor of ophthalmology at the New York University College of Medicine; member of the American Academy of Ophthalmology and Otolaryngology and the American Academy of Ophthalmology; fellow of the American College of Surgeons; served during the World War; surgeon to the New York Eye and Ear Infirmary; visiting surgeon, department of ophthalmology, Bellevue Hospital; aged 53; died, January 10.
- Joseph Forrest Burnham @ Lawrence, Mass.; Harvard Medical School, Boston, 1901; member of the House of Delegates of the American Medical Association in 1915 and secretary of the staff of the Lawrence General Hospital; formerly of the Essex North District Medical Society; aged 70; died, January 26, in the Phillips House of the Massachusetts General Hospital, Boston, of carcinoma of the prostate.
- Alexander Crump Kirby @ Little Rock, Ark.; Washington University School of Medicine, St. Louis, 1917; assistant professor of pediatrics at the University of Arkansas School of Medicine; served during the World War; formerly member of an advisory council of the maternal and child health division, and consultant to the state board of health; aged 47; died, Nov. 4, 1939.
- Henry Lawrence Swain @ New Haven, Conn.; Yale University School of Medicine, New Haven, 1884; clinical professor of otology emeritus at his alma mater; member, past president and secretary of the American Laryngological Association; laryngologist to the New Haven Dispensary and Hospital; aged 75; died, January 11, of esophageal varix and cirrhosis of the liver.
- Thomas Le Roy Lauderdale @ Ranger, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1913; fellow of the American College of Surgeons; past president of the Eastland County Medical Society; served during the World War; a medical director of the West Texas Clinic and Hospital; aged 50; died, January 1, of pulmonary tuberculosis.
- Kimball Bannister, Phoenix, Ariz.; Northwestern University Medical School, Chicago, 1914; member of the Arizona State Medical Association; fellow of the American College of Surgeons; on the staffs of St. Joseph's and Good Samaritan hospitals; aged 50; died, January 30, of injuries received in an automobile accident.
- George Alexander Van Wagenen, St. Petersburg, Fla.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1871; for many years medical director of the Mutual Benefit Life Insurance Company; aged 94; died, January 2, of pyelonephritis and chronic myocarditis.
- Jesus Maria Armaiz @ Vega Baja, P. R.; Hahnemann Medical College and Hospital of Philadelphia, 1911; formerly vice president of the Puerto Rico Medical Association; medical superintendent of a hospital bearing his name; aged 52; died, Dec. 23, 1939, in Santurce of typhoid and bronchopneumonia.
- Walker Washington @ Staten Island, N. Y.; Bellevue Hospital Medical College, New York, 1885; past president of the Richmond County Medical Society; for many years president of a bank in Tottenville; on the staff of the Richmond Memorial Hospital; aged 79; died, Dec. 10, 1939.
- Thomas Joseph Perkins, Baton Rouge, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1892; member of the Louisiana State Medical Society; formerly superintendent of the East Louisiana State Hospital, Jackson; aged 70; died, Dec. 30, 1939, of heart disease.
- James D. Jordan, Portsmouth, Ohio; University of Louisville (Ky.) Medical Department, 1894; member of the Ohio State Medical Association; on the staff of the Portsmouth General Hospital; aged 69; died, January 2, in a hospital at Dalton, Ga., of injuries received in an automobile accident.
- Isidore J. Weida, Emmaus, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; for many years member of the board of health; aged 73; died, Dec. 23, 1939, of hypertension and coronary disease.
- George Lawrence McCormick @ Beaver Falls, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; on the staffs of the Providence Hospital, Beaver Falls, and the Beaver Valley General Hospital, New Brighton; aged 59; died, Dec. 31, 1939, of coronary occlusion.
- Wilkes H. Knolle, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1891; member and past president of the Louisiana State Medical Society; president of the Orleans Parish Medical Society; aged 69; died, January 7, of coronary thrombosis.
- Carl Ralph Martin, Fountain City, Tenn.; Chattanooga (Tenn.) Medical College, 1910; member of the Tennessee State Medical Association; served during the World War; formerly bank president, aged 58; died, January 8, in St. Mary's Hospital, Knoxville, of bronchopneumonia.
- Claude Terrell Poole, St. Pauls, N. C.; North Carolina Medical College, Charlotte, 1907; member of the Medical Society of the State of North Carolina; served during the World War; aged 53; died, January 8, in the Veterans Administration Facility, Columbia, S. C.
- Carl Welfley Frantz @ Confluence, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; formerly bank president; owner and medical director of a hospital bearing his name; aged 55; died, Dec. 20, 1939, of carcinoma of the prostate with metastases.
- Robert Henry Beverly, Springfield, Ill.; Bennett Medical College, Chicago, 1912; member of the Illinois State Medical Society; state district health superintendent for the state department of health; aged 61; died, January 22, in St. John's Hospital.
- John Baker Haggard, Fort Leavenworth, Kan.; University of Tennessee Medical Department, Nashville, 1892; served during the World War; aged 71; died, January 9, in the Veterans Administration Facility, Wadsworth, of arteriosclerotic heart disease.
- Benjamin A. Gipple, Alden, N. Y.; University of Buffalo Medical College, Chicago, 1906; at one time city physician of Davenport, Iowa; aged 63; died, Dec. 2, 1939, in the Veterans Administration Facility, West Los Angeles, of brain tumor.
- Jefferson Duddleston Blything, Fontana, Calif.; Rush Medical College, Chicago, 1906; served during the World War; aged 57; died, January 6, of coronary thrombosis.
- Thomas Brown Johnson @ Indianapolis; University of Maryland School of Medicine, Baltimore, 1906; served during the World War; for many years on the staff of the Methodist Hospital; aged 71; died, January 6, of coronary thrombosis.
- Theodore Marion Du Bose Sr., Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1881; member of the South Carolina Medical Association; aged 81; died, Dec. 25, 1939, of myocarditis and arteriosclerosis.
- Joseph Henry Hauck, Terre Haute, Ind.; Eclectic Medical Institute, Cincinnati, 1899; member of the Indiana State Medical Association; served during the World War; aged 65; died, January 4, in the Union Hospital, of diabetes mellitus.

Bernard Bertram Wormser ☉ Scranton, Pa.; Jefferson Medical College of Philadelphia, 1902; served during the World War; on the staffs of the Scranton State and Hahnemann hospitals; aged 62; died, Dec. 28, 1939, of heart disease.

William H. Ditmars, Jonesville, Mich.; Detroit College of Medicine, 1896; member of the Michigan State Medical Society; president of the school board; aged 66; died, January 3, in the Hillsdale (Mich.) Hospital of cerebral hemorrhage.

Thomas Walker Tait, Philadelphia; Jefferson Medical College of Philadelphia, 1888; formerly on the staffs of the Methodist Hospital and St. Agnes Hospital; aged 76; died, Dec. 13, 1939, of granulocytopenia and peritonsillar abscess.

Charles Elliott Ristine, Knoxville, Tenn.; University of Pennsylvania Department of Medicine, Philadelphia, 1870; member of the Tennessee State Medical Association; Civil War veteran; aged 94; died, January 10, of pneumonia.

Frederick Edwin Tully, San Diego, Calif.; Marion-Sims College of Medicine, St. Louis, 1895; member of the California Medical Association; served during the World War; aged 71; died, Dec. 6, 1939, of coronary disease.

Elias H. Witmer, Lancaster, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1877; member of the Medical Society of the State of Pennsylvania; aged 86; died, Dec. 13, 1939, of arteriosclerosis.

Robert Lee Hardwick, Mount Vernon, Ind.; Missouri Medical College, St. Louis, 1886; for many years county health officer; aged 76; died, January 5, of cerebral hemorrhage and carcinoma of the colon.

Ernest Darnall, Colt, Ark.; Memphis (Tenn.) Hospital Medical College, 1908; member of the Arkansas Medical Society; aged 56; died, January 2, in the Baptist Hospital, Memphis, of cerebral hemorrhage.

Julian Lloyd Waller, San Francisco; College of Physicians and Surgeons of San Francisco, 1904; member of the California Medical Association; served during the World War; aged 69; died, Nov. 15, 1939.

Napoleon Landry, Fitchburg, Mass.; School of Medicine and Surgery of Montreal, Que., Canada, 1893; aged 79; died, Dec. 21, 1939, in Lunenburg, of cerebral hemorrhage and arteriosclerosis.

James West Hingston, Chicago; Hahnemann Medical College and Hospital, Chicago, 1882; aged 81; died, January 29, in the West Suburban Hospital, Oak Park, Ill., of hypertrophy of the prostate.

Nathan Caldwell Doane, New Market, Tenn.; Tennessee Medical College, Knoxville, 1894; on the staff of the Jefferson Hospital, Jefferson City; aged 73; died, January 8, of coronary occlusion.

John P. Hawkins, Anniston, Ala.; Chattanooga (Tenn.) Medical College, 1894; member of the Medical Association of the State of Alabama; aged 70; died, January 1, of angina pectoris.

Solomon Wells Churchill, New York; Bellevue Hospital Medical College, New York, 1897; aged 80; died, January 15, in St. Luke's Hospital of cerebral hemorrhage and bronchopneumonia.

Claude E. Earle, Anderson, S. C.; College of Physicians and Surgeons, Baltimore, 1886; aged 79; died, Dec. 23, 1939, in the Anderson County Hospital of carcinoma of the prostate.

Milton H. Brown, Morgantown, W. Va.; Baltimore Medical College, 1893; member of the West Virginia State Medical Association; aged 71; died, January 10, of coronary thrombosis.

James Ernest Brooks, Chicago; Bennett Medical College, Chicago, 1910; member of the Illinois State Medical Society; aged 56; died, January 4, of arteriosclerosis and chronic nephritis.

Luther James Shepley, North Westport, Mass.; College of Physicians and Surgeons, Boston, 1902; served during the World War; aged 63; died, Dec. 19, 1939, of coronary occlusion.

David Thomas Bailey, Cleveland; University of Wooster Medical Department, Cleveland, 1900; aged 65; died, January 21, in the Cleveland-Clinic Hospital of carcinoma of the pancreas.

George Abner Hammond, Dothan, Ala.; Baltimore Medical College, 1884; member of the Medical Association of the State of Alabama; aged 80; died, January 4, of chronic myocarditis.

William Thomas Joiner, Pittsview, Ala.; Atlanta Medical College, 1891; aged 80; died, January 8, in the City Hospital, Columbus, Ga., of uremia and hypertrophy of the prostate.

George Monroe Hite, Amelia, Ohio; Eclectic Medical College, Cincinnati, 1918; member of the Ohio State Medical Association; aged 50; died, January 20, of heart disease.

Edward L. Wilkinson, Jacksonville, Fla.; College of Physicians and Surgeons, Baltimore, 1885; aged 79; died, Nov. 6, 1939, in St. Luke's Hospital of mesenteric thrombosis.

Thomas N. Ellis, Knoxville, Tenn.; Kansas City (Mo.) Hospital College of Medicine, 1885; aged 79; died, January 3, of myocarditis, chronic nephritis and hypertension.

Benjamin Augustus Crichlow, Charleston, W. Va.; Howard University College of Medicine, Washington, D. C., 1902; aged 66; died, Dec. 31, 1939, of gastric ulcer.

Welcome Turner Jones, Little Rock, Ark.; Western Reserve University Medical Department, Cleveland, 1893; aged 74; died, January 12, of mitral insufficiency.

Alfred G. Shissler, Shamokin, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; aged 73; died, Dec. 9, 1939, of carcinoma of the lung.

Herman M. Doty, Chagrin Falls, Ohio; Western Reserve University Medical Department, Cleveland, 1873; aged 91; died, Dec. 29, 1939, of bronchopneumonia.

Louise Patterson, Glendale, Calif.; American Medical Missionary College, Chicago, 1899; aged 73; died, Nov. 17, 1939, of arteriosclerosis and myocarditis.

Llewellyn Fleet Luckett ☉ Washington, D. C.; Columbian University Medical Department, Washington, 1895; aged 68; died, Dec. 31, 1939, of heart disease.

William Eric A. D. Von Der Goltz, New York; Universität Basel Medizinische Fakultät, Switzerland, 1887; aged 77; died, Dec. 17, 1939, of heart disease.

Thomas Moore Acken ☉ New York; University of the City of New York Medical Department, 1893; aged 72; died, Dec. 11, 1939, of cerebral hemorrhage.

Maude Waterhouse Abbott, Canton, Ohio; Eclectic Medical Institute, Cincinnati, 1886; aged 79; died, January 2, of cerebral hemorrhage and arteriosclerosis.

Tandy Bartow Harrison, Charleston, Miss.; Memphis (Tenn.) Hospital Medical College, 1892; aged 77; died, Dec. 31, 1939, of cirrhosis of the liver.

Max Grossman, Brooklyn; Long Island College Hospital, Brooklyn, 1902; aged 58; died, January 5, in the Kings County Hospital of intestinal obstruction.

Catharine Phoebe Hayden, Ashland, Mass.; University of Colorado School of Medicine, Denver, 1894; aged 81; died, Dec. 26, 1939, of arteriosclerosis.

Franklin Noll, Jenkintown, Pa.; Jefferson Medical College of Philadelphia, 1892; aged 67; died, Dec. 16, 1939, of encephalomalacia and bronchopneumonia.

George Estus Garwood, Toledo, Ohio; Toledo Medical College, 1900; served during the World War; aged 75; died, January 5, of paralysis agitans.

Benjamin Iverson Hicks, Vicksburg, Miss.; Louisville (Ky.) Medical College, 1896; aged 68; died, January 16, of uremia and heart disease.

Albert F. Snell, Cleveland (licensed in Tennessee in 1829 and in Ohio in 1897); aged 83; died, Dec. 27, 1939, of arteriosclerotic heart disease.

William F. Birss, Grand Rapids, Mich.; Saginaw Valley Medical College, Saginaw, 1902; aged 61; died, January 13, of coronary thrombosis.

Charles Wesley Davis, Cincinnati; Medical College of Ohio, Cincinnati, 1887; also a druggist; aged 77; died, Dec. 29, 1939, of myocarditis.

James Joseph McMahon ☉ Port Allegany, Pa.; Jefferson Medical College of Philadelphia, 1927; aged 40, died, Dec. 9, 1939, of heart block.

James Whitworth, Clarksville, Tenn.; University of Nashville Medical Department, 1898; aged 63; died, Nov. 25, 1939, of angina pectoris.

Charles Damsky ☉ Lynn, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1921; aged 45; died, Dec. 3, 1939, in Boston.

Robert Kirksey, Pickens, S. C.; College of Physicians and Surgeons, Baltimore, 1891; aged 71; died, Dec. 29, 1939, of pneumonia.

Clark Kirksey Thomas, Findley, Ohio; Toledo Medical College, 1897; aged 75; died, Dec. 25, 1939, of acute dilatation of the heart.

Martin L. Sellers, Los Angeles; Barnes Medical College, St. Louis, 1899; aged 69; died, Nov. 24, 1939, of arteriosclerosis.

THE BAKER HOSPITAL AND
J. L. STATLER, M.D.
tory of Norman Baker
uent ref-

When an individual who is totally devoid of any scientific training, let alone any formal medical education, attempts to treat patients who are suffering from a serious disease, he must comply with certain regulations—or at least make a pretense of complying with such regulations. The usual technic is to associate with him some one who does hold a license to practice medicine. Baker was eventually stopped in Iowa. The pretext which he used in trying to avoid difficulty with the law by leasing his hospital to Statler was not sufficient to save the institution. Obviously Baker could not have gained much headway if he had not had associated with him a man who was licensed to practice, a man who could legally place after his name the initials "M.D." What price was paid to Statler for supporting the ideas and carrying out the work in the Baker Hospital is not known, but it certainly should have been a goodly sum, for

Statler, by joining Baker, made himself a pariah in his chosen profession. At least temporarily he is, of course, not practicing medicine; so far as the Bureau can determine, he is now behind bars pending any subsequent arrangements that may be made in connection with his sentence, which, as it will be recalled, was one year and one day in jail.

Here, then, is a man—recognized as a physician—whose cooperation was necessary to perpetrate the Baker fraud. Although graduating from a reputable medical school, he abused his right and privilege to practice medicine. Once, no doubt, he listened to the high precepts and ideals which are impressed on the student of medicine. Could he have thought of them as he signed death certificates for those who died in the Baker Hospital? Does he ponder on the past as he sits in jail awaiting developments in a case in which he was found guilty of fraud? It is a pitiful spectacle—a man fully qualified, both by medical training and by legal recognition of that medical training, to become an important factor in the life of any community in which he settled finds himself instead behind bars, after having signed hundreds of death certificates for persons who were told that their cancers would be cured. There is a lesson in the life of this charlatan that every student in our medical schools today should learn.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Fisher's Diuretic Alternative.—Mrs. E. Heinz, Denver. Composition: Chiefly water, alcohol, sugar and small amounts of plant material extracts. Fraudulently claimed to cure dropsy and skin diseases, dissolve gallstones, strengthen the nerves, etc.—[N. J. 30223; June 1939.]

Fisher's Gastric Assimilator.—Mrs. E. Heinz, Denver. Composition: Alcohol, water and plant material extracts. Fraudulently represented for chronic stomach disorders, pain of childbirth, etc.—[N. J. 30223; June 1939.]

Fisher's P P P.—Mrs. E. Heinz, Denver. Composition: Essentially water, alcohol, epsom salt and flavoring. Fraudulently represented as "an emergency remedy" for conditions not named.—[N. J. 30223; June 1939.]

G. S. I. Gly-So-Iodonate.—National Medical Research Laboratories, Milwaukee. Composition: Essentially water, alcohol, glycerin, common salt and small quantities of carbonates, sulfates, iodides, phosphates and borates, with traces of formaldehyde and iodoform. Adulterated because its strength fell below the professed quality or standard under which it was sold, namely, an antiseptic. Misbranded because representations made for it as an "antiseptic surgical first aid" and as a remedy for burns on scalp and skin were fraudulent.—[N. J. 30220; June 1939.]

Miller's (Dr.) Intraclean.—Miller Co., Inc., Newark, N. J. Composition: Essentially broken senna leaves and huckthorn bark, with a small amount of agar agar. For nervousness, stomach, kidney and liver disorders, obesity, high blood pressure, backache, etc.—[N. J. 30224; June 1939.]

Mother Hubbard Camphorated Oil.—Mother Hubbard Products Co., Inc., Chicago. Composition: Not more than 10.6 per cent of camphor. Adulterated because it did not contain 19 per cent of camphor as required for camphorated oil by the U. S. Pharmacopeia, and misbranded because fraudulently represented as an effective treatment for asthma and croup.—[N. J. 30025; May 1939.]

Mother Hubbard Remedies Laxative Head-Cold Tablets.—Mother Hubbard Products Co., Inc., Chicago. Composition: Not more than 0.913 grains of acetanilid per tablet. Adulterated because not containing the 2 grains of acetanilid per tablet declared on the package, and misbranded because claimed to contain no "harmful habit-forming drugs," whereas they did contain acetanilid.—[N. J. 30025; May 1939.]

Orchotine Tablets.—Hudson Pharmacal Co., Inc., Union City, N. J. Composition: Animal tissue, probably glandular in nature, with $\frac{1}{16}$ grain of extract of nux vomica per tablet. Adulterated because not containing active principles of testicular glands as represented, and misbranded because fraudulently represented to cure nervous exhaustion, sexual apathy and "subefficiency" in men.—[N. J. 30222; June 1939.]

Tensol.—Tensol Co., Elmira, N. Y. Composition: An aqueous solution of a mild silver proteinate compound. Fraudulently represented to cure tennel disorders, diphtheria, quinsy, adenoids, etc.—[N. J. 30225; June 1939.]

Correspondence

"PRIMARY TUBERCULOUS INFECTION ATTACK RATES"

To the Editor:—In the Dec. 16, 1939, issue of THE JOURNAL, page 2204, Stewart and his associates published a paper on "Primary Tuberculous Infection Attack Rates." Among the group studied were nurses training in (1) a general hospital with no tuberculosis service, (2) a general hospital with a six weeks tuberculosis service, which I shall designate as hospital A, (3) a general hospital with a three months tuberculosis service, which I shall designate as hospital B, and (4) a six weeks service in a tuberculosis sanatorium and the hospital where the nurses receive the remainder of their three years training, which will be designated as C.

The report attempts to compare the infection rate obtained from the six weeks service in a tuberculosis sanatorium with the three year infection rate in the two general hospitals which have a tuberculosis service. This is manifestly an unscientific and unfair comparison.

According to one of the collaborators (Boynton, Ruth E.: Incidence of Tuberculous Infection in Student Nurses, *Am. Rev. Tuberc.* 39:671 [May] 1939), 29.9 per cent of the student nurses entering the training school at hospital C during the years 1933 to 1937 were tuberculin positive at the beginning of their hospital experience, and during the first year 17.9 per cent of those who were tuberculin-negative became tuberculin positive, even though they had not yet had their tuberculosis service. In a personal communication, Boynton informed me that 60.9 per cent of the nurses who entered the training school at hospital C were tuberculin positive at the end of their training. This includes six weeks in a tuberculosis sanatorium.

Her report of the percentage of nurses who were tuberculin positive at the beginning and end of training means that seventy of each hundred nurses were tuberculin negative at the beginning of training while only thirty-nine were tuberculin negative at the end of training. The difference between the seventy and the thirty-nine is thirty-one. This represents the number of negative nurses out of each hundred who became infected during their three year training period. This is 43 per cent of the original negative group of seventy. Dividing that by 3, representing the number of years spent in training, as was done for hospitals A and B, one finds that hospital C has an average annual increase in infection of 14.3 per cent in contrast to 19.8 per cent for hospital A and 29.7 per cent for hospital B. When the six weeks contact at the sanatorium is considered by itself, the authors place "the crude annual primary infection attack rate" at 115.4 per cent instead of at 14.3 per cent. This is arrived at by multiplying ten weeks, the time interval between the tuberculin test prior to beginning the six weeks service in the sanatorium and the tuberculin test three or four weeks after the service is ended, by 5.2, which is the number of times ten weeks will go into a year. In using this figure the authors consider the whole ten weeks as spent in the tuberculosis environment, even though only six weeks of that time is spent at the sanatorium.

The authors also mention the fact that a tuberculosis service has been established "at the Minneapolis General Hospital, where attempts are being made to perfect a technic which will prevent attendants from acquiring infections with tubercle bacilli while working with tuberculous patients." This will be designated as hospital D. The technic used consists, in the training of changing a cap, mask and gown and scrubbing the hands and arms for two minutes before the care of each patient in the same ward. The tuberculosis service consists of one thirty bed floor in the contagious unit. While the student nurse is assigned to

the contagious unit for six weeks, she does not spend more than two weeks of that time on the tuberculosis floor. However, not more than one half of the beds on this floor are set aside for the care of tuberculosis, and at times there have been as few as two tuberculous patients in that unit. Therefore her two weeks service there cannot be considered the equivalent of more than a one week service in a tuberculosis sanatorium, if that long.

In spite of that, another of the collaborators, Myers, at the meeting of the Canadian Tuberculosis Association held in Winnipeg in September 1939, reported that during a certain twelve months period ten of the eighty-nine nurses who were tuberculin negative at the beginning of their contagious service, two weeks of which is spent in the tuberculosis unit, were tuberculin positive at the end of that service. However, he stated that four of the ten had cared for open cases of tuberculosis elsewhere than in the tuberculosis service and so should be excluded from the study. This reduced the number who apparently acquired a tuberculous infection in the new tuberculosis service to six. This was 6.7 per cent of the eighty-nine. He stated further that it was the lowest "crude annual primary infection attack rate" that he knew of in connection with any tuberculosis service in the country, and he attributed the so-called low rate to the type of contagious technic used.

No allowance was made at hospitals A, B or C for any source of infection outside of the tuberculosis service. That is not necessary for hospitals A and B, because the nurses spend their entire three years there and whatever infection they acquire outside the tuberculosis service would be included in their average annual infection rate. However, it is a very important consideration for hospital C, as the nurses spend only six weeks in the tuberculosis service and then go back to their regular environment. In this instance the tuberculosis service is charged with all the infection that developed during the period under consideration (ten weeks).

The second point deals with the statement made by the authors on the effect of the length of contact with tuberculous patients on the infection rate when, in comparing the "crude annual primary infection attack rates" in hospitals A and B, the authors state that "the increases in infections recorded for the two groups of nurses who worked in wards for tuberculous patients were roughly proportional to the length of time each group spent in this type of service." Accepting that statement as true, one can then multiply 6.7 per cent, the so-called annual infection rate following a one week exposure in the tuberculosis service in hospital D by 6, representing a six weeks contact at the sanatorium for nurses from hospital C. This results in a six weeks infection rate of 40.2 per cent at hospital D in contrast to one of 22.2 per cent for hospital C. Using the same statistical method as the authors did in arriving at the crude annual primary infection rate of 115.4 per cent for hospital C, one would multiply the 40.2 per cent by 5.2, as that is the number of times ten weeks will go into fifty-two weeks. This gives the student nurses who have worked in the tuberculosis unit at hospital D a "crude annual primary infection attack rate" of 209.04 per cent.

This rate is, of course, impossible for at least two reasons: (1) more than 100 per cent of nurses cannot become infected, and (2) even though the nurses work in the tuberculosis service for a year there would be a few who would not react positively to the tuberculin test. Still it is no more absurd than is the rate of 115.4 per cent, which the authors give as the "crude annual primary infection attack rate" for the tuberculosis service at the sanatorium. In spite of its absurdity, I believe it does prove rather conclusively that the elaborate contagious technic in use in the tuberculosis unit of hospital D has not been any more effective, if as effective, in preventing the transmission of infection from patient to nurse than the technic in use at the sanatorium.

It seems to me that when one begins to compare "crude annual primary infection attack rates" one should use comparable facts in arriving at conclusions and not compare a three year period for one hospital with only a six weeks tuberculosis service in another hospital. When like is compared with like, there is some basis for judging the results, but when dissimilar things are compared one has no justification whatever in drawing any particular conclusions from the study.

E. S. MARIETTE, M.D., Oak Terrace, Minn.
Superintendent, Glen Lake Sanatorium.

GRADE A VERSUS GRADE B MILK IN NEW YORK CITY

To the Editor:—Mayor LaGuardia's public proclamation urges substitution of grade B for grade A milk to combat the high cost of the de luxe product. Two issues are involved: cost and quality. Economy is a great revenue to thrifty adults but a selective virtue to helpless infants. Grade A milk is still the most economical food for infant nutrition when compared with the total cost of equivalent nutrients. If it can be made available at less cost, so much the better. Until then, superior milk should remain the choice for infant feeding.

Grade A is preferable to grade B milk for infants because of superior bacteriologic control. The former averages about 50,000 bacteria per cubic centimeter before pasteurization while the latter averages about 250,000 per cubic centimeter. The bacterial count of milk is an index of the sanitary quality. Although milk with a high bacterial count is not necessarily harmful to health if the flora is innocuous, milk with a low bacterial count may be unsuitable if charged with pathogenic organisms. Metabolic studies of artificially fed infants have shown that boiled milk with a high bacterial count is less efficiently utilized and more apt to produce digestive disturbances than boiled milk with a low bacterial count.

Sanitary supervision of the milk supply contributed greatly to lowering the incidence of gastrointestinal diseases in infants. Why retrogress? If grade A milk is to be eliminated from the sanitary code, certified milk with less than 500 bacteria per cubic centimeter should be advocated for infants and grade B milk for older children and adults.

I. NEWTON KUGELMASS, M.D., New York.

SENSITIVITY TO SOLUTION OF POSTERIOR PITUITARY

To the Editor:—The January 20 issue of *THE JOURNAL* carries a letter by Bernard Seligman citing a case of hypersensitivity to solution of posterior pituitary and mentioning McMann's report in the Oct. 14, 1939, issue. Both cases showed general collapse. I do not know whether urticaria following injection of this substance, but without the collapse symptoms, is rare but cite the following:

For the induction of labor, my wife was given 1 minim (0.06 cc.) of solution of posterior pituitary hypodermically, and the injection was followed in ten or fifteen minutes by an urticarial eruption. The eruption was general, caused a great itching and was relieved by epinephrine after half an hour. Following delivery she was given solution of posterior pituitary again by mistake (the nurse had been ordered not to give it); the urticaria again followed and was again relieved by epinephrine. There was no respiratory distress, the pulse remained strong, regular and at about the same rate during the period of urticaria; the epinephrine was given to relieve the itching, not because any circulatory failure was impending. Pituitary had been given after two previous deliveries but without any unusual reaction.

A. L. ABBETT, M.D., Oakland, Calif.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TUBERCULIN TESTING METHODS

To the Editor:—There has been a great deal of agitation in regard to the method of tuberculin testing of human beings. Some advocate the Pirquet, others the Mantoux and still others the patch test. I recently read an article by Wolff, of San Francisco, on the technic of a percutaneous test in which he stated that the results of his aintment were practically equal to the Mantoux test. I have since gone through the literature but have been unable to find verification of this work. Might I have your opinions of the value of patch tests with the various aintments in use and the relation of this procedure to the Mantoux test.

Edward M. Jeppson, M.D., Ogden, Utah.

ANSWER.—In 1890 and for thirteen years thereafter, tuberculin for testing was administered by the subcutaneous method. The doses were large and constitutional reactions manifested by such symptoms as temperature elevation and malaise were important in determining the presence of tuberculosis.

In 1903 Pirquet conceived the idea of making a shallow scarification in the skin and applying tuberculin in order to produce a local reaction and avoid constitutional manifestations. In 1907 Pirquet (*Deutsche med. Wchnschr.* 33:865, 905, 1907) published the results of his work. Unfortunately, the test became known as the Pirquet test rather than the cutaneous tuberculin test. Pirquet's method of administering tuberculin has been extensively used. The chief objection to the administration of tuberculin by Pirquet's method is that there is no way of knowing how much tuberculin actually reaches the abraded area. Its administration is also time consuming. Moreover, in some cases the tuberculin is promptly rubbed from the area by the patients and so little is left as to result in no reaction. However, today in the hands of experts such as Slater, of Minnesota, and Chadwick, of Massachusetts, the cutaneous tuberculin test of Pirquet is satisfactory in determining the presence or absence of sensitivity of tissues to tuberculo-protein.

In 1908 (*München. med. Wchnschr.* 55:217, 1908) a method of administering tuberculin was reported which consisted of using a pomade of equal parts of hydrous wool fat and pure tuberculin. This was rubbed over an unabrased area of skin about 5 cm. in diameter for one minute. The area was then exposed to the air for ten minutes and no dressing was applied. Unfortunately, this became known as the Moro test rather than the transcutaneous or percutaneous test. Since Moro presented his work a number of physicians have slightly modified his method of administration. For example, Lovett (*Am. J. Dis. Child.* 37:918 [May] 1929) found that by vigorously rubbing an area of skin over the sternum with ether much of the oil was removed from the pores. Therefore, when a piece of concentrated old tuberculin the size of a pinhead was rubbed into the area, more entered the pores and a much better result was obtained than by Moro's original method.

In 1933 Wolff (*Am. Rev. Tuberc.* 27:308 [March] 1933) reported a modification of the percutaneous test of Moro, which consisted of first cleansing an area in the paravertebral region between the eighth and eleventh thoracic vertebrae with green soap and water, and after drying it was bathed with benzine to remove the oil from the pores. To the area he applied a special tuberculin ointment the size of a pea. This was covered with a piece of adhesive tape 2 inches square, which was tightly applied. By this method Wolff reported good results from the standpoint of determining the presence of sensitivity to tuberculin.

Vollmer (*Am. J. Dis. Child.* 54:1019 [Nov.] 1937) has introduced another modification of the percutaneous test of Moro which is designated as the tuberculin patch test. Its administration consists of cleansing an area of skin with acetone, ether or benzine, after the removal of any hair that may be present. The patch to be applied consists of a strip of tape to which has been attached two squares (1 by 1 cm.) of thin filter paper saturated with undiluted tuberculin and dried. These are placed on the tape 1 cm. apart. The adhesive side of the tape is protected with crinolin, which must be removed before the application of the patches. The tape is then tightly applied with the patches adjacent to the skin, where it remains for forty-eight hours. It is best to allow another forty-eight hours to elapse after the removal of the patches before reading the test.

Vollmer and Goldberger (*Am. J. Dis. Child.* 57:1272 [June] 1939) have reported that this test is equal in determining the

presence of sensitiveness to tuberculin to the intracutaneous test, when 0.1 mg. of old tuberculin is used. Unfortunately the intracutaneous test is not considered complete until the individual who has failed to react to smaller doses has been tested with a full milligram of tuberculin. When the second dose is not administered, the test may fail in as many as 10 to 20 per cent of persons whose tissues are sensitized to tuberculin. To overcome this discrepancy, Vollmer has recommended that all persons who do not react to the patch test have an intracutaneous test administered with a full milligram of tuberculin.

Objections which have been presented to the tape and patch methods of administering tuberculin are: 1. It is time consuming. 2. Many persons object to having adhesive tape on the skin and a few are highly sensitive to adhesive tape. Many complain of the itching sensation produced by the tape. 3. With excessive perspiration, such as may occur among students in gymnasiums, athletes or adults whose work causes perspiration, the adhesive tape may actually fall off. 4. Many persons dislike to omit bathing for forty-eight hours while the tape is on the skin. 5. The subject who does not react to the patch test must be seen five times: (a) to apply the tape, (b) to remove it, (c) to observe the area forty-eight hours later, (d) to administer the intracutaneous test and (e) to observe the area for presence or absence of reaction.

In 1908 Mantoux (*Compt. rend. Acad. d. sc.* 149:355, 1908) presented a method of administering tuberculin which consisted of introducing with a fine hypodermic needle into the layers of the skin a measured amount of tuberculin. This, unfortunately, is spoken of as the Mantoux test rather than the intradermal or intracutaneous tuberculin test. Usually 0.1 cc. of a dilution of 1:10,000 or 1:1,000 of tuberculin is administered as the first dose, that is, 0.01 or 0.1 mg. of tuberculin. If no reaction occurs in from forty-eight to seventy-two hours the test is repeated by using 0.1 cc. of a dilution of 1:100. This amounts to 1 mg. of tuberculin. If no reaction occurs the individual being tested is thought to be free from tuberculous infection. When purified protein derivative is used, the corresponding doses are administered.

There are persons who object to instrumentation, including needles, for any purpose. However, where good health education work has been done, these persons are greatly in the minority. The fact that this minority refuses the test is not a good argument against it because its administration differs little or not at all from the method employed in giving Dick or Schick tests. Moreover, in administering such immunizing substances as toxoid, the same sized needle is used as in the administration of the tuberculin test.

The advantages of the intracutaneous method are that a measured amount of tuberculin is introduced and remains exactly where we desire it to be; it cannot be removed by the subject. No tape or bandaging of any kind is necessary. Little time is consumed in administering the test. Where large numbers are to be tested and there is good organization, a single experienced physician is able to administer several hundred tests an hour.

This has become the standard method of administering tuberculin in this country and is strongly recommended by practically all organizations engaged in tuberculosis work.

SUBSTANCES INTERFERING WITH TESTS FOR ALCOHOL IN URINE

To the Editor:—Will you kindly tell me whether or not there is anything that will give the alcohol test in urine besides alcohol?

B. C. Boston, M.D., Waterloo, Iowa.

ANSWER.—Reducing substances are found in distillates from normal urine to the extent of about 0.003 per cent. The quantity is too small to interfere with the test for alcohol when used to confirm alcoholic influence. The reducing substances have not been completely identified, but Harger has shown that they arise at least in part during the process of distillation. It has been said that ether, acetone and chloroform may give false readings for alcohol. These substances have been proved to be without influence in the test for alcohol when potassium bichromate is used as a direct oxidizing agent according to a technique described by Heiser in the *American Journal of Clinical Pathology* 4:182 (March) 1934. Since this paper was written it has been discovered that formaldehyde, which may appear in urine from the ingestion of methenamine, may reduce potassium bichromate to a slight extent. In order to get some specific information, 1 Gm. (15 grains) of methenamine was taken by mouth and repeated urinalyses revealed a maximum reduction of potassium bichromate corresponding to 0.021 per cent of alcohol by weight. Formaldehyde in the urine can be detected with ease and can be removed from the distillate.

VALVULAR HEART DISEASE AND PREGNANCY

To the Editor:—A woman aged 27 who has valvular heart disease (mitral) with same pulmonary edema is about seven months pregnant. I am worried as to which is best: to protect the mother by an early delivery in about thirty days or to protect the baby and let the mother go to term. She rests two hours, is up two and uses four pillows to sleep, taking 1½ grains (0.1 Gm.) of digitalis daily. She has blood pressure of 96 systolic and 76 diastolic and a pulse rate of 108; her feet are not swelling, and on gross examination the urine was almost normal. If she goes to a hospital, what is the best way to induce premature labor?

Nathaniel J. Bucklin, M.D., Roodhouse, Ill.

ANSWER.—It seems probable that the pulmonary congestion or edema present in this young woman with mitral stenosis is due not to heart failure but to the combined and mechanical effect of mitral stenosis, tachycardia and the extra work of pregnancy. It will probably be safe to allow her to go to term if she remains quiet in bed and chair in order to keep the heart rate down and uses digitalis for the same reason. The heart strain will become less in the last month and it is probable that she will deliver herself. There is likely to be more strain caused by inducing premature labor now than by carrying out the measures that have been mentioned.

TONSIL REMOVAL BY WARING SUCTION METHOD

To the Editor:—Will you please advise me as to how the Waring suction technic and method for the removal of tonsils is regarded by laryngologists—its merit or advantages, if any, and its disadvantages, if any.

R. A. Young, M.D., DuBois, Neb.

ANSWER.—The Waring suction technic and method for the removal of tonsils is not in as widespread use as dissection and the various forms of the Ring instrument technic. The advantages claimed are that blood and infectious secretions are kept out of the field of operation and the possibilities for inhalation are thereby much reduced. From the standpoint of trauma, the average operator would probably obtain with this method a smoother tonsillar fossa and be much less apt to tear tissues than would be the case in an indifferently performed dissection operation. This would not hold for the experienced dissector or user of instruments such as the Sluder and the Beck tonsillectomes.

SULFANILAMIDE IN LEUKEMIA

To the Editor:—Are there any contraindications or therapeutic reasons for the use of either sulfanilamide or sulfapyridine in acute myelogenous leukemia?

M.D., Illinois.

ANSWER.—There is no reason to believe that the use of either sulfanilamide or sulfapyridine is contraindicated in acute myelogenous leukemia, provided a definite indication for its use in the control of an infectious process arises. Neither of the drugs has had any effect in the control of either acute lymphatic or myelogenous leukemia, and there is no reason to believe that they will depress the granulocytic element in the bone marrow unless the patient happens to have a peculiar idiosyncrasy to these drugs. Any treatment with either of these drugs designed to affect the white blood cells directly is highly experimental, and its therapeutic value is extremely questionable.

GLASS EATING

To the Editor:—In *Queries and Minor Notes* in The Journal Dec. 23, 1939, page 2341, was an inquiry from M.D., Connecticut, relative to eating glass. I was called to a nearby fire-house to witness a Negro about 40 years old who, in my presence, (1) chewed and swallowed two safety razor blades, (2) swallowed several 8 penny nails, (3) chewed and swallowed several large pieces of broken milk bottle glass, (4) inserted and closed a safety pin through the glans penis and (5) inserted a safety pin through the left biceps muscle. I looked into his mouth. His teeth were ground down flat. The buccal mucosa was thickened and grayish. He told me he was never operated on for abstraction and passed everything he swallowed, only rarely resorting to digital extraction. This practice had been engaged in for the previous fifteen or twenty years.

Anthony Ambrase, M.D., Newark, N. J.

REACTION TO SOLUTION OF POSTERIOR PITUITARY

To the Editor:—I recently had a reaction to solution of posterior pituitary in a multipara to whom I had administered it in four previous deliveries. On January 19 at 3 a.m. I administered 0.5 cc. of solution of posterior pituitary. After about five minutes the patient complained about itching of the back. An alcohol rub did not stop it. A rash quickly spread over all the skin, which became scarlet with both small and large wheals. This was followed by choking and a feeling of a hardness of the tongue. A quick injection of epinephrine worked rapidly. After twenty-four hours the mother and baby were in good condition. However, the site of the injection, about the size of a half dollar (30 mm.), remained swollen and red.

G. E. Poolazzi, M.D., Canton, Ohio.

Book Notices

Supervision in Public Health Nursing. By Violet H. Hodgson, Supervisor, Outpatient Tuberculosis Nursing, New York State Department of Health. Cloth. Price, \$2.50. Pp. 376, with 21 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1939.

Every public health nurse should read Violet Hodgson's new book and for every supervisor or administrator concerned with public health nursing the book is an essential. The basic theme underlying this work is that successful supervision is based on democratic principles and that the exercise of arbitrary authority fails to secure the best performance from the staff nurse. One would hardly venture to disagree with this principle; it is idealistic and in keeping with our national philosophy. Yet we owe, in modern nursing, much to the traditional military system of organization, which has given us an understanding of the importance of clear lines of responsibility and authority. In stating the ideal democratic basis for supervision in public health nursing Mrs. Hodgson has perhaps overstressed its case. The two chapters dealing with the teaching function of the supervisor are excellent and give a proper emphasis to this phase of the supervisor's work; it was particularly wise to include here the laws of learning. In a book written for specialists who are expected to have a background in their field, one would not expect to find quite so much detailed description of historical developments. However, this is not a weakness in the book—it is merely time consuming for the reader, who will most likely be a busy supervisor or other professional worker. Since, as the author points out, there has been a great increase of public health nursing under official auspices, one could expect greater space and emphasis given to supervision under conditions found in public agencies. Civil service and problems of supervision connected with it are not discussed at all. This is a real and unfortunate omission. The book is the most authoritative word on its subject. It deserves, and will receive, wide attention and it undoubtedly will become an influential factor in shaping relationships and directions taken in public health nursing agencies throughout the land.

The Diagnosis and Treatment of Diseases of the Esophagus. By Porter P. Vinson, B.S., M.A., M.D., Professor of Bronchoscopy, Esophagoscopy and Gastroscopy, Medical College of Virginia, Richmond, Virginia. Cloth. Price, \$4. Pp. 224, with 98 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, Publisher, 1940.

This is a good book and a much needed one. For years most patients with diseases of the esophagus have been receiving poor treatment largely because there are so few men in the world who have enough material of this one type to become expert in diagnosis and treatment. Unfortunately also, for some curious reason, some of the men who have written the few available books and articles on the esophagus seem to have been unaware of the fact that in 1898 Russell, of England, devised a simple apparatus by means of which strictures in the esophagus and spasmodic contractures at the cardia can be dilated with a high degree of safety. A recently published book on the esophagus still advocated the retrograde attack on cardiospasm through a fistula in the stomach. As Vinson says (p. 14), gastrostomy is associated with a surprisingly high mortality; it rarely provides grateful palliation in cases of cancer of the cardia and it is quite unnecessary in most of the cases of benign obstruction in esophagus and cardia. Excellent results can be secured without it. Dr. Vinson began writing his book with the tremendous advantage of having had an enormous experience in this field. For years he, Dr. Henry Plummer and Dr. Herman Moersch took care of the patients with esophageal diseases drawn from the huge material seen at Rochester, Minn. Perhaps the commonest of these diseases is cardiospasm, and this can usually be relieved easily by the Russell-Plummer technic. First the patient is made to swallow a thread. This finds its way through the narrow place and passes on down into the small bowel, where it becomes sufficiently anchored so that traction can be made on it. Olive shaped dilators are then passed over the thread and down through the obstruction. After the narrow place has been dilated to size 60 French, the hydrostatic dilator of Russell is brought into play. The preliminary use of the sound so

completely eliminates the danger of rupture of the esophagus that in the last 450 cases Vinson has had no death from this cause. Strangely enough, strictures due to carcinoma of the esophagus can also be dilated and with only a small risk. Such dilation gives many patients a large degree of relief. There are several chapters in the book on the rarer diseases of the esophagus, hysterical dysphagia, esophageal diverticula, cicatricial stenoses, foreign bodies, and stricture of the esophagus due to pressure from outside. Vinson states that almost all patients with benign stricture of the esophagus can be relieved completely and permanently of difficulty in swallowing if the treatment which he outlines is promptly employed and faithfully carried out. Usually the esophagus has to be dilated at intervals for two years. Gastrostomy rarely has to be done. In the book there are two valuable chapters on the technic of esophagoscopy and on the general handling of patients. This little volume should greatly improve the treatment now being given to patients with esophageal disease throughout the world.

Beiträge zur Frage der normalen Genese der Blutzellen. Die Entstehung der fötalen Erythromyelopoese in Leber und Milz und das Vorkommen von Myelocyten in der normalen Milz und Thymus. Von Arne Bertelsen. Denno Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København, 1938. Paper. Pp. 272, with 36 illustrations. Copenhagen: Levin & Munksgaard; Ejnar Munksgaard, 1938.

The work is a doctor's thesis, which probably accounts for the long and repeated discussions of theories regarding origin and relations of blood cells and for the extensive tabular matter. The book is devoted to the problem of extramedullary erythromyelopoiesis in the spleen, liver and thymus of normal human fetuses of the seventh, eighth and ninth months, the prematurely born, the newly born and the infant, child and adult, with the object of determining the normal limits of extramedullary blood formation in these age groups. The material was by far the most extensive and best controlled of any series used for study of this problem. Trauma in one form or another was the most frequent cause of death. Only cases in which the necropsy revealed no pathologic changes were included in the series regarded as normal. A few pathologic cases were studied for comparison with the corresponding normal age groups. While it is generally conceded that extramedullary myelopoiesis is to be seen in late fetal stages, only a few investigators believe that it extends beyond the newborn under normal conditions. Bertelsen's observations for liver, spleen and thymus are in agreement with those of the latter authors. His proof is submitted in great detail; it includes thirty-six photomicrographs and slightly more than 100 pages of tables in which the number of hematopoietic foci and differential counts of normoblasts and myelocytes seen in a specified number of microscopic fields (Leitz objective 3, ocular 8) of sections are listed. The results are discussed from the standpoint of the leading hematologic theories, with the conclusion that the unitarian theory gives the best explanation of the observations. The literature pertaining to the problem is reviewed critically and in detail.

The liver was studied in twenty-one fetuses of the seventh month, twenty-seven of the eighth month, twenty-two of the ninth month, thirty-two newborn (full term) and two infants 14 days and 6 weeks of age. Seven premature infants and nine malformed fetuses were studied. The author found hematopoietic foci in the connective tissue of the portal canals and in the hepatic trabeculae and sinusoids of the lobules. The majority of intralobular foci are in the sinusoids, but some are located between the liver cells of the trabeculae and show no connection with the sinusoids. These foci are composed of myeloblasts, normoblasts in different stages of development, and a few myelocytes. The extravascular location of many of these foci is not in harmony with the view of Sabin and Doan that erythropoiesis is always intravascular and that the cells originate from endothelium. The author did not see any evidence favoring an endothelial origin of any of the blood cells. Both myelocytes and granulocytes could be traced to the "hemocytoblasts" (myeloblasts), which are most numerous in the fetal stages. Myelocytes are most abundant in the portal foci. While the number of foci is reduced from the seventh fetal month to birth, their size and cellular composition remains constant. All the livers of thirty-two newborn infants contained intralobular hematopoietic centers, and in nine of them there were from twenty-five to eighty-five

such centers for each microscopic field. From this the author concludes that liver hematopoiesis must be more extensive than is shown from his series to be normal before a diagnosis of fetal erythroblastosis or hydrops congenitus is justified. Hepatic foci were still present in the two weeks and six weeks old infants. As normal material from age 6 weeks to 3 years was not available, it was impossible to determine the age at which liver hematopoiesis terminates. It was not seen in normal children and adults. Intralobular hematopoiesis was reduced in the seven premature infants studied, but the portal foci were large and the number of their myelocytes increased. Extra-uterine life, therefore, seems to suppress intralobular erythropoiesis and to favor myelopoiesis in the portal tissue. Local intravascular development of myelocytes was noted in the fetal livers, and in these livers the extravascular erythropoietic centers were most numerous, which favors the Mollier view that hematopoiesis in the liver is at first extravascular and later intravascular. Bertelsen could find only an occasional extravascular focus in the liver lobules of the newly born.

All the spleens of the premature and newborn infants of this series showed evidence of myelopoiesis and erythropoiesis in both pulp and follicles. In the pulp the cells were scattered or occurred in small groups, often in the marginal zone of the follicles. From the seventh fetal month to full term birth the normoblasts were reduced from an average of 24 per immersion field to 12, and they and the myelocytes were found in the spleens of all newborn infants. The erythroblasts and myelocytes are in different stages of development and so must be assumed to be of local origin. Eosinophilic myelocytes were found in all of forty-one spleens in cases of traumatic death at ages of from 4 to 89. A few neutrophilic and basophilic myelocytes were also seen, and a few myelocytes were located in the follicles. Erythroblasts were not found in this age group. The granulopoietic function is therefore retained to extreme old age, while the development of red cells terminates soon after birth, although the exact period could not be determined.

Erythroblasts were not seen in the thymus of the adult in a single case. An occasional erythroblastic focus was seen in this organ at the end of fetal life, while only single scattered erythroblasts were observed in the late fetuses. Myelocytes, however, were numerous and were found at all ages as long as the organ persists. Eosinophilic myelocytes predominated, as was also true of the spleen. Myelopoiesis is not reduced at the end of fetal life as it is in the other organs showing extramedullary hematopoiesis, and it is more extensive than in the other organs. An occasional myelocyte was found even at age 65. The myelocytes were seen to be in various stages of development and they were associated with large, basophilic hemocytoblasts and so must have been of local origin. The presence of small, dark "trachy-chromatic" nuclei identical with those of the smaller lymphocytes is interpreted as evidence for the direct origin of some of the myelocytes from lymphocytes. In the fetus the myelocytes are associated with more hemocytoblasts, which are probably derived from the perivascular and septal mesenchyme, than is the case in the adult. A few myelocytes with lymphocytic nuclei were also seen in the fetus. From these observations the author concludes that the thymus continues to function as a granulopoietic organ and that in the adult the myelocytes are derived largely from lymphocytes, and in the fetus from both lymphocytes and mesenchyme.

Failure of the Circulation. By Tinsley Randolph Harrison, M.D., Associate Professor of Medicine, Vanderbilt University School of Medicine, Nashville, Tennessee. Second edition. Cloth. Price, \$4.50. Pp. 502, with 61 illustrations. Baltimore: Williams & Wilkins Company, 1939.

This edition is considerably longer than the initial one chiefly because it includes an extensive section on angina pectoris covering about seventy pages. The author emphasizes the importance of sudden death when the myocardium is in need of oxygen. He refers to experimental work of several authors regarding the production of ventricular fibrillation by anoxia. Harrison condemns such diagnoses as pseudo-angina. In the remainder of the book the general pattern of the first edition is followed. Much of the material comes from earlier papers of the author and his associates. This section contains sound descriptions of the origin of the cardinal symptoms of congestive heart failure, dyspnea and edema. Harrison champions the "backward failure" theory advanced by James Hope a century ago. The evidence

presented seems to justify this contention. The entire book is well documented with more recent references. There is an index. The chief merit of both editions is the application of physiologic observations to clinical practice. Repeatedly the author brings up minor points in treatment which are logical outgrowths of experimental work. This "physiologic" attitude toward the care of patients makes the book desirable reading for all students specializing in diagnostic or cardiac work. The volume would help the preparation for examination by the American Board of Internal Medicine. It will find application as supplementary reading for students in physiology. Its general utility as a textbook for reference in applied cardiovascular physiology remains preeminent. No physician would fail to learn much by reading it in continuity.

Health Facts for College Students: A Textbook of Individual and Community Health. By Maude Lee Etheredge, M.D., Dr.P.H., Professor of Hygiene and Medical Adviser for Women, University of Illinois, Urbana. With a foreword by Ray Lyman Wilbur, M.D. Third edition. Cloth. Price, \$2. Pp. 410, with 65 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

College students as well as others are being constantly bombarded, through newspapers, moving pictures and general conversation, with medical propaganda and advice concerning diet and other facts about health. Hence it seems important that they be supplied with simple and authoritative material on personal and public health. This book is not meant to be a work of a highly technical nature. Rather it is designed to furnish health facts to college students so that they may maintain the highest degree of efficiency and physical and mental hygiene. It is easily read and includes just enough technical material so that the college student will understand the purpose of the author. The illustrations are easily understood. There are included chapters on alcohol and its relation to the nervous system, smoking, narcotics, heredity, friendship and marriage, allergy and mental health and hygiene. The book can be recommended for college students and should help them in deriving important facts concerning health.

Proctoscopic Examination and Diagnosis and Treatment of Diarrheas. By M. H. Stretcher, M.S., M.D., Assistant Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. Price, \$3. Pp. 149, with 39 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1940.

Part I gives a clear, concise and well illustrated method for the performance of proctoscopic examination. It is based on the author's large experience in this field and offers many practical suggestions which will facilitate the examination. Part II includes a classification of diarrheas from the etiologic standpoint and a brief discussion of treatment. The author has attempted to cover too much ground in too short a space. The classification, treatment and references are incomplete, so that the second portion of the book suffers by comparison with the first portion.

The Essentials of Medical Treatment. By David Murray Lyon, M.D., D.Sc., F.R.C.P., Professor of Clinical Medicine, The University, Edinburgh. Cloth. Price, 15s. Pp. 448, with 19 illustrations. Edinburgh & London: Oliver & Boyd, 1939.

In the preface to this new book from the Edinburgh school it is stated that the author's primary object has been "to survey the whole range of therapeutic measures, and demonstrate the full resources of modern medicine." Unfortunately it does not seem that these objectives have been fully attained. A considerable amount of information regarding approximately 120 disease states is conveyed, but the recitative manner of its delivery is so redolent of the old style of didactic clinical lecture that one is taken back most unpleasantly to the lecture amphitheater, now happily passé in most leading American schools. The book reads pleasantly—some of the old clinical lectures were delightful to listen to—but the pages do not spring to life and offer help to one who consults them, as those of a textbook of therapeutics might reasonably be asked to do. So thoroughly detached indeed is the entire work that the reviewer failed to find (others with greater diligence might succeed) a single instance in which the experience of the author or some other doctor or group of doctors is specifically referred to. Thus of course there can be no bibliography. The index seems to be adequate.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Privileged Communications: Privilege Once Waived Ceases to Exist.—The insured instituted three separate suits in the circuit court of St. Louis, Missouri, against the Metropolitan Life Insurance Company, apparently to collect certain benefits allegedly due him under an insurance policy. All three suits involved substantially the same issues. One suit was tried and was pending on appeal. The others were pending in the trial court. For use in the pending suits, the Metropolitan Life Insurance Company sought to obtain the deposition of a Denver physician. A commission was duly appointed in Denver but the physician refused to testify, relying on the protection of a statute making communications between physicians and patients privileged. The insurance company then petitioned the Denver district court for a subpoena requiring the physician to testify and to produce certain books, records and memoranda. The court sustained the refusal of the physician to testify and discharged him from the order to show cause why he should not be held guilty of contempt. The Supreme Court of Colorado was then asked by the insurer to pass on the question.

The testimony sought from the physician related primarily to hospital records showing the illness of the insured during the years 1925 to 1927 in a Denver hospital. The only question before the Colorado court was whether the privilege had been waived. In determining this question, said the court, the law of the forum governs, that is, the law of the state in which the suits on the insurance policy were pending, Missouri. In the suit that had already been tried in Missouri the insured, without objection, permitted two physicians employed at the Denver hospital during the years involved, 1925 to 1927, to testify about his illness. In the opinion of the Supreme Court of Colorado, this constituted a waiver of the privilege as applied to the testimony sought in the present proceedings. The purpose of the privilege, the court pointed out, is "to encourage confidence and to preserve it inviolate." When the patient permits, without objection, the confidential information to become public at a public trial, the reason for the privilege ceases to exist. Moreover, under the Missouri authorities, a waiver of privilege established through the testimony of one physician extends to all who have attended the patient for the same ailment, regardless of the time of such consultations, attendance or treatments. The privilege once waived ceases to exist, and when a waiver of privilege is once made it is general and not special and its effect cannot properly be limited to a particular purpose or a particular person. The trial court, therefore, should have required the physician to appear before it and to testify. The judgment of the trial court was therefore reversed and the cause remanded with directions to proceed in accordance with the views expressed by the Supreme Court.—*Metropolitan Life Ins. Co. v. Kaufman (Colo.)*, 87 P. (2d) 758.

Medical Practice Acts: Scope of Chiropractic in Iowa.—A licensed Iowa chiropractor, the defendant in this case, was enjoined by the Supreme Court of Iowa from practicing physical therapy and electrotherapy, from administering colonic irrigations and from prescribing diets. *State v. Boston*, 278 N. W. 291 (abstr. J. A. M. A. 111:1592 [Oct. 22] 1938). A rehearing was granted the defendant by the Supreme Court and a supplemental opinion rendered.

Section 2555 of the Iowa Code defines chiropractors as:

Persons who treat human ailments by the adjustment by hand of the articulations of the spine or by other incidental adjustments.

Section 2559 of the Code provides that a license to practice chiropractic shall not authorize the licensee to practice operative surgery or osteopathy, or to administer or prescribe any drug or medicine included in materia medica. The defendant chiropractor argued that the laws of Iowa make a chiropractor a member of the healing professions, with authority to use any agency in healing the sick except those agencies the use of which is expressly prohibited. But, said the Supreme Court in

this supplemental opinion, the practice of medicine and surgery is the practice of the healing art, and, unless restrictions be placed thereon by the legislature, the whole field of medicine and surgery is open to the practitioner. On the other hand, the practice of chiropractic, although recognized as a branch of the healing art, is only one form of the practice, within well defined limits, of the science of healing as such practice is defined by section 2555 of the Code. The legislature has prescribed, the court said, the method of healing which may be used by chiropractors and has further specified, by section 2559, other methods which may not be used. If section 2559 broadened the field in which the chiropractor may practice, the court continued, and if he has the right to go outside the restrictions and employ other methods not therein prohibited, then the whole field of medical science is open to him except as prohibited in that section. The court expressed belief that the practice of medicine and surgery includes physical therapy, electrotherapy, colonic irrigations and the prescribing of diet and that therefore chiropractors may not lawfully employ such modalities.

The defendant urged that the ruling of the court would bar the use of mechanical appliances or common instruments by barbers and others. The classes mentioned, the court pointed out, are not engaged in the practice of medicine or of healing nor are they holding themselves out to the public as healers. The reason for all laws restricting the activities of professions is the protection of the public, and the legislature has seen fit to enact laws governing the practice of the various forms of the art of healing, permitting each practitioner to follow his profession according to its established principles. Those persons who are authorized to practice one form of the art may not encroach on another form for which they have no authority from the state.

The Supreme Court, therefore, adhered to its former decision in this case.—*State v. Boston (Iowa)*, 284 N. W. 143.

COMING MEETINGS

- Academy of Physical Medicine, Richmond, Va., Apr. 24-26. Dr. Herman A. Osgood, 144 Commonwealth Ave., Boston, Secretary.
- Alabama, Medical Association of the State of, Birmingham, Apr. 16-18. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.
- American Association for the Study of Goiter, Rochester, Minn., Apr. 15-17. Dr. W. Blair Mosser, 133 Biddle St., Kane, Pa., Secretary.
- American Association of Anatomists, Louisville, Ky., Mar. 20-22. Dr. E. R. Clark, Dept. of Anatomy, Univ. of Pennsylvania School of Medicine, Philadelphia, Secretary.
- American Association of Pathologists and Bacteriologists, Pittsburgh, Mar. 21-22. Dr. Howard T. Karsner, 2085 Adelbert Rd., Cleveland, Secretary.
- American College of Physicians, Cleveland, Apr. 1-5. Mr. E. R. Lovelock, 4200 Pine St., Philadelphia, Executive Secretary.
- American Physiological Society, New Orleans, March 13-16. Dr. F. T. Bard, Johns Hopkins Medical School, Baltimore, Secretary.
- American Society for Experimental Pathology, New Orleans, March 13-16. Dr. Paul R. Cannon, Dept. of Pathology, University of Chicago, Chicago, Secretary.
- American Society for Pharmacology and Experimental Therapeutics, New Orleans, March 13-16. Dr. G. Philip Grabfield, 319 Longwood Ave., Boston, Secretary.
- American Society of Biological Chemists, New Orleans, Apr. 13-17. Dr. C. G. King, Dept. of Chemistry, Univ. of Pittsburgh, Pittsburgh, Secretary.
- Arizona State Medical Association, Tucson, Apr. 18-20. Dr. Leslie P. Kober, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Fort Smith, Apr. 13-17. Dr. W. R. Brockman, 602 Garrison Ave., Fort Smith, Secretary.
- Federation of American Societies for Experimental Biology, New Orleans, Mar. 13-16. Dr. D. R. Hooker, 19 West Chase St., Baltimore, Secretary.
- Georgia, Medical Association of, Savannah, Apr. 23-26. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.
- Louisiana State Medical Society, New Orleans, Apr. 22-24. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, Apr. 23-25. Dr. Richard T. Shackelford, 1211 Cathedral St., Baltimore, Secretary.
- Minnesota State Medical Association, Rochester, Apr. 22-24. Dr. F. F. Souster, 493 Lowry Medical Arts Building, St. Paul, Secretary.
- Nebraska State Medical Association, Omaha, Apr. 22-25. Dr. P. F. Adams, 416 Federal Securities Building, Lincoln, Secretary.
- Northern Tri-State Medical Association, Battle Creek, Mich., Apr. 9-11. Dr. E. Benjamin Gillette, 320 Michigan St., Toledo, Ohio, Secretary.
- Pacific Coast Surgical Association, Portland, Ore., Apr. 3-6. Dr. Glenn Bell, University of California Hospital, San Francisco, Secretary.
- Southeastern Surgical Congress, Birmingham, Ala., Mar. 11-13. Dr. Benjamin T. Beasley, 701 Hurt Building, Atlanta, Ga., Secretary.
- Tennessee State Medical Association, Chattanooga, Apr. 9-11. Dr. H. B. Shoulders, 706 Church St., Nashville, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

59:1-218 (Jan.) 1940

*Treatment of Pneumococcal Infections in Children with Sulfapyridine. H. S. Christian, G. M. Jorgensen and Catherine Ellis, New York.—p. 1.

Dietary and Metabolic Studies of Eskimo Children With and Without Dental Caries, Including Studies of Metabolic Balances of Calcium, Phosphorus and Nitrogen. E. H. Siegel, L. M. Waugh and M. Karshan, with technical assistance of Clare Lowenberg and Mary Segall, New York.—p. 19.

Biochemical Studies of Saliva of Eskimos Correlated with Dental Caries and Occurrence of Salivary Calculus. M. Karshan, E. H. Siegel and L. M. Waugh, with technical assistance of Mary Segall, New York.—p. 39.

Study of Feet of Infants and Children. A. Bloxson, Houston, Texas.—p. 45.

Weltmann Reaction and Sedimentation Rate During Rheumatic Fever of Childhood. R. I. Klein, S. A. Levinson and P. Rosenblum, Chicago.—p. 48.

*Treatment of Impetigo Contagiosa with Rubber Containing 8-Hydroxyquinoline. M. Seldowitz, Brooklyn.—p. 67.

Modification of Smallpox Vaccination in Susceptible Infants: Use of Specific Convalescent Serum. J. Greengard and A. M. Wolf, Chicago.—p. 76.

*Pneumococcal Pneumonia of Type XIV in Children Treated with Specific Serum. J. G. M. Bullova and M. Gleich, New York, with assistance, in the statistical study, of J. J. Cohen and Constance Lehair.—p. 84.

Attempts to Enhance Virulence of *Haemophilus Pertussis* by Serial Passage in Guinea Pigs. J. A. Toomey and W. S. Takacs, Cleveland.—p. 94.

Glutathione and Red Cells in Blood in Infancy and in Childhood. Helen McNamara and M. J. E. Senn, New York.—p. 97.

Growth and Chemical Composition of Human Skeleton. W. W. Swanson and V. Iob, Chicago.—p. 107.

Growth, Development and Care of the Child. H. Bakwin and Ruth Morris Bakwin, New York.—p. 112.

Lipodystrophy: Report of Case, with Metabolic Studies. J. S. Harris and R. Reiser, Durham, N. C.—p. 143.

Sulfapyridine in Pneumococcal Infections of Children.

—During a seven months period, Christian and his associates treated 140 children with pneumococcal infections by means of sulfapyridine. Two hundred mg. of the drug per kilogram of body weight was given in divided doses during the first day and 100 mg. per kilogram a day thereafter. Except to a few of the older children, who preferred to swallow the tablets whole, the drug was administered by crushing the tablets and suspending the powder in a small amount of water, milk, fruit juice or honey. When vomiting occurred within an hour after a regular dose, the dose was repeated. One hundred patients had pneumococcal pneumonia. Seven of the 100 patients had otitis media with a purulent discharge from one or both ears, and a number of others had otitis media without rupture of the tympanic membranes. All had pneumococci in their upper respiratory passages and all had x-ray changes consistent with pneumonia. The blood for culture was taken from all patients, usually on admission and in many cases also just before treatment was started. Only four children had positive blood cultures. Twenty-seven per cent of the children were under 1 year of age, and 45 per cent were under 2 years. Discussing the mortality and complications, the authors say that one infant, who had mongolism and congenital heart disease, died after four days of treatment. Two patients had otitis media after administration of sulfapyridine was stopped, but on further treatment their ears improved without rupture of the tympanic membranes. Although 73 per cent of the patients vomited during treatment, only 57 per cent vomited more than once, and in a few cases vomiting was as severe before treatment was started as during it. Cyanosis has not been easy to evaluate because several of the patients were cyanotic at the time treatment was started. The cyanosis of some patients seemed to be definitely due to the drug. Further, the authors discuss the use of sulfapyridine in

pneumococcal disorders other than pneumonia. Of four patients who had early pneumococcal empyema, two who had received serum recovered with sulfapyridine therapy; the other two required rib resection in spite of treatment with sulfapyridine. Seventeen children with acute pneumococcal otitis media were treated with sulfapyridine. The average duration of the otitis media at the time treatment was started was four days and the longest duration was eighteen days. Other pneumococcal infections treated with sulfapyridine were primary pneumococcal peritonitis, osteomyelitis, meningitis, laryngotracheobronchitis, infections of the respiratory tracts without roentgenologic signs of pneumonia and pneumococcal wound infection. Five patients with nephrosis and one with asthma who were known to have been carriers of pneumococci were treated and in five cases the therapy was successful within two weeks. Some of the limitations of sulfapyridine were demonstrated in the two cases of pneumococcal meningitis in which death occurred and in a case of pneumonia in which bacteremia persisted during five days of treatment before antipneumococcal serum was given. Studies on absorption and excretion of sulfapyridine are presented and the authors direct attention to the occasional need for a preparation of sulfapyridine which can be given parenterally.

Impetigo Contagiosa.—According to Seldowitz, it has been demonstrated by Kahn and Carroll that rubber containing 8-hydroxyquinoline exhibits certain bacteriostatic properties, particularly in reference to the staphylococcus. In view of the bacteriostatic properties of this rubber base combination, it occurred to the author that the material might find therapeutic application in cases of certain types of pyogenic infections, mainly impetigo contagiosa. A study was made of its effect on thirty-eight children suffering from this infection. The children were divided into two groups. The first included those showing the bullous type of lesion, which was more common in young infants; the second group embraced those presenting the confluent, crusted type of lesion, which occurred more commonly in older children. The group with bullous lesions consisted of eleven patients. In the second group, those with crusted lesions, the infection often began with a small erythematous macule which rapidly developed into a flat pustular vesicle, and this was rapidly transformed into a dry crust resting on an inflamed base. Frequently a seropurulent discharge oozed from beneath the margins of the crust. In applying the rubber base substance, care was taken not to disturb the crusts mechanically. The importance of this has been strongly emphasized by Newman. The lesions were covered with a thin layer of gauze, and the rubber was applied over the gauze. The dressings were held in situ with adhesive plaster and were changed at intervals of from two to four days. The gauze was employed to absorb any secretions which might accumulate beneath the rubber, such as those resulting from liquefaction of the crust or from actual exudation from the lesion itself. The medicated rubber was found to operate as efficiently through the layers of gauze as when placed directly over the lesions. Some of the patients were treated at once with the medicated rubber. For control purposes others were subjected to a preliminary period of treatment with various agents. Summarizing the results of his treatment, the author says that thirty-five of thirty-eight patients were successfully treated with rubber containing 8-hydroxyquinoline. The average time for the disappearance of the crusts was three days. The skin returned to a normal appearance in an average of eight days. The lesions in three of the thirty-eight cases were refractory to this form of therapy.

Specific Serum in Children with Pneumococcal Pneumonia of Type XIV.—According to Bullova and Gleich, the acceptance of serum therapy for children with pneumonia has been slow. Because of skepticism, the alternation of specific serum therapy was continued at the authors' hospital until evidence of its value was available in an adequate series of cases. Their observations have extended over ten years. Serum was administered when available to alternate patients. Except in nine cases the serum was administered intramuscularly, usually into the upper outer quadrant of the buttock, and the area was massaged for five minutes. After describing the determination of the type of pneumococcus the authors say that pneumococcus type XIV was found in 16.8 per cent of the cases. Its frequency

varies from time to time. From 1929 to 1936 an average of from twenty-two to twenty-three cases were observed each year. In the season 1937-1938, forty-nine cases were observed. Intramuscular injection of serum (followed by massage) was used in sixty-two cases; nine patients received serum intravenously, and three of them died. Twenty patients were treated with rabbit serum and two with horse and rabbit serum in the last two years and four months; all recovered. The dose was about the same in all cases, being from 50,000 to 150,000 units. The death rate in the entire series of cases in which serum was not used was 14.4 per cent. With serum the mortality was 4.2 per cent, a reduction of 70 per cent. The authors reach the conclusion that pneumococcus type XIV is the organism most frequently found in infants and very young children with pneumonia. The mortality is higher before the age of 3 years than after this age. With the use of specific serum in adequate amounts, fewer patients die, more patients with bacteremia recover, the disease is shortened and complications are fewer.

Indications for Direct Laryngoscopy.—According to Jackson, direct laryngoscopy provides the only means of examining the larynx of infants and young children and is indicated in the presence of any symptom referable to the larynx in a child. Obstructive laryngeal dyspnea, stridor, wheezing, hoarseness or aphonia call for direct laryngoscopy as the most important diagnostic procedure and often the only means of treatment. Direct laryngoscopy has shown that the most common cause of stridor in infancy is congenital deformity of the epiglottis and supraglottic aperture. The condition is rarely serious and is generally outgrown during the second year of life without treatment. However, it is extremely important to diagnose it and to exclude other conditions which do require treatment and may prove fatal if not treated; for example, congenital subglottic webs, papillomas, bilateral abductor paralysis or dislocation of the arytenoids can be diagnosed accurately only by direct laryngoscopy. Obviously, a foreign body in the larynx of a child, as in an adult, constitutes an indication for direct laryngoscopic removal. In neonatal asphyxia, direct laryngoscopy should always be done for aspiration of laryngeal and tracheal secretions and to exclude high obstruction as a cause. Adult patients requiring direct laryngoscopy may be divided into two classes: those in which the larynx is imperfectly visualized by the laryngeal mirror and those in which the larynx

is well visualized by the mirror but some condition is revealed which calls for instrumental manipulation, such as biopsy, the removal of a benign tumor or dilation. An overhanging or deformed epiglottis is the most common cause of difficult visualization by the indirect method, though some other anatomic condition or an exceptionally intolerant throat may be at fault.

Potassium Chlorate and Poliomyelitis.—Experiments performed by Saucier and Stewart, designed to repeat the work reported by Contat, Arthus, Spycher and Debat in which they claimed to have obtained evidence of a specific protective action from potassium chlorate against experimental poliomyelitis in monkeys, show to the contrary that potassium chlorate is of no value against the development or course of experimental poliomyelitis in monkeys.

- *Clinical Significance of Bleeding of First Trimester of Pregnancy. F. C. LaBrecque, Waterbury.—p. 676.

Bleeding of First Trimester of Pregnancy.—LaBrecque says that examination of the records of 510 patients seen in the antepartum clinic of the Massachusetts Memorial Hospital reveals that only 17.2 per cent, or only eighty-eight women saw a physician for the first time during the first trimester of pregnancy. Moreover, 215 patients did not see a physician until the last trimester and twenty-four patients were not seen by a physician until they were at term. Despite the attention focused on antepartum care by the medical and lay press, patients are still seeing their physicians or visiting the maternity clinics much too late in pregnancy. About 40 per cent of all patients during the child bearing age have, at one time or another, bleeding as a complication during the first three months of pregnancy. Ti-

bleeding may be classified as (1) pseudomenstruation, (2) cervical (cervicitis, endocervicitis, erosion, polyp and carcinoma), (3) intra-uterine (abortion and hydatidiform mole) and (4) extra-uterine (ectopic pregnancy). The author concludes that carcinoma of the cervix does occur as a complication early in pregnancy and must be seriously considered when the bleeding is cervical in origin. The medical and lay press must continue education of the public regarding early antepartum care—which means the reporting of the patient to her physician within two weeks of missing a menstrual period. The causes of first trimester bleeding are classified and discussed as to diagnosis and treatment.

Pseudo-Dick Reactions.—In a search for a substance sufficiently potent to be considered a likely cause of pseudo-Dick reactions, Huntington states that filtrates of cultures of the hemolytic streptococcus contain little streptococcus protein, and the hypothesis which considers such protein a frequent cause of pseudo-Dick reactions appears untenable. The activity of a filtrate of a nonscarlatinal streptococcus in the skin did not appear to depend on cellular disintegration and differed in its great heat stability and in other respects from that of preparations of streptococcus protein. No agent could be found, other than scarlatinal toxin, which had the potency necessary to induce reactions to one or two skin test doses of the scarlatinal filtrates used. On the whole, the results tend to suggest that at least in the age group studied (from 6 to 15 years) pseudo-Dick reactions to serum-free filtrate are unusual, and control filtrates heated for two hours at 100 C. should be of value in detecting them when they occur.

New Type of Calcaneal Spur.—Vasko directs attention to a type of spur formation on the posterior aspect of the os calcis, which to his knowledge has not been described before. He discovered such spurs on the posterior superior aspect of the os calcis at operation on two patients suffering from an achilles bursitis. The clinical aspects were those of an achilles bursitis consisting of swelling, aching, tenderness, and increased local temperature. Pressure of the shoe produced discomfort and walking was painful, especially climbing upward. Conservative treatment consisting of rest, immobilization and physical therapy proved unsuccessful and so after several weeks operative removal of the bursae was done. At operation the author found enlarged edematous bursae as was expected, but after their removal spurs which were small, rough and sharp were found on the posterior superior aspect of the os calcis. These protruded as much posteriorly as superiorly. Obviously they constituted a rough surface over which the tendon had to slide and which probably caused the bursitis. Whether the spur or the bursitis came first is not known. The first case reported by the author reveals that recovery may occur without removal of the spurs. In this case the heels remained thickened posteriorly but were free from symptoms two years after the operation. In the second case the spurs were chiseled off, but the ultimate result is not known because the patient was not heard from again.

Ascorbic Acid in Commercial Milks.—Woessner and his associates determined the ascorbic acid content of regular commercial samples of milk as related to the quantity present in the milk at the time of milking. They found that samples of raw,

certified, certified Guernsey and certified vitamin D milks are, on the average, only a little below the fresh milks in ascorbic acid content, indicating that commercial raw and certified milks as delivered to the consumer lose only a small amount of their antiscorbutic potency. Likewise, samples of commercial pasteurized milks analyzed on an average contained only about half as much ascorbic acid as fresh raw milks and less ascorbic acid than the commercial unpasteurized milks. In pasteurized and unpasteurized milks the amount of dehydroascorbic acid was less than the ascorbic acid. Commercial pasteurized vitamin D milks in which the potency has been increased by incorporating vitamin D concentrates directly into the milk by homogenization fell below the average value of ordinary pasteurized milks with respect to the ascorbic acid content. On the other hand if the vitamin D content has been increased by feeding the animal irradiated yeast, the antiscorbutic property falls on a par with the average value for commercial pasteurized milks. This would indicate that homogenization tends to destroy ascorbic acid. Mineral modified milk is low in ascorbic acid.

Vitamin B₁ and Morphine Abstinence Symptoms.—The idea that morphine may increase the requirement for vitamin B₁, as alcohol does, and that the heightened irritability of the nervous system observed after withdrawal of morphine may be due to a deficiency of vitamin B₁ led Fitzhugh to study the effect of crystalline vitamin B₁ on the morphine abstinence symptoms of albino rats. He found that thiamin (for two days previous to and after withdrawal of morphine) not only decreased the irritability before the permanent withdrawal of morphine but also prevented the usual increase in irritability that follows morphine withdrawal. This effect was not due to any toxic action of the large doses of thiamin chloride used.

 Pyelitis in Pregnancy. T. M. Stevens, Portland.—p. 18.
 Postoperative Infections Following Abdominal Operations. G. A. Tibbetts, Portland.—p. 24.

Treatment of Neonatal Asphyxia.—From a study of the customary treatment of neonatal asphyxia in sixty-three obstetric teaching centers of the United States and Canada, Flagg finds that carbon dioxide with oxygen is in general use, that aspiration is regarded as essential and that the use of heat is frequently overlooked. This should always be applied to protect the baby from exposure. Sharp differences of opinion exist regarding the use of alpha lobeline and other drugs as respiratory stimulants. When intracranial hemorrhage is suspected, lumbar puncture is advocated and the injection of whole blood into the buttocks is recommended. Mouth to mouth insufflation is commonly employed as a method of artificial respiration when mechanical facilities are not available. Intracardiac injections are used as a last resort and are not popular. The use of blind intubation in accordance with the technic of de Lee is common practice in many clinics. The technic of direct laryngoscopy, intubation, suction and insufflation is not generally understood or applied when indicated. Confusion exists as to the sequence in which intracranial hemorrhage occurs; it is claimed as both a cause and a result of asphyxia. The baby that has shown signs of asphyxia should be carefully observed after it is returned to the nursery. The important question of atelectasis

is raised and the need of research is indicated. There is a strong sentiment in favor of popularizing to the profession and the public certain general information relative to neonatal asphyxia, with special feeling that frequent sedation administered to the mother is responsible for much of the neonatal asphyxia which is encountered and that the elimination or the reduction of this routine sedation will do much to prevent asphyxia.

Surgical Treatment of Mental Disorders.—Freeman and his associate have modified the original Moniz surgical technic for the correction of mental abnormalities. Freeman finds that prefrontal lobotomy, carried out surgically, produces a certain change in the personality of the individual, characterized by a reorientation in the direction of extroversion and a reduction in introversion. It eliminates obsessive thinking, it reduces self-consciousness and it promotes satisfaction with self and surroundings. Fear of the future is no longer present. Following operation the patient behaves differently; his behavior seems to depend to some extent on his original makeup and to some extent on the amount of frontal lobe that is still in connection with the rest of the brain. The most satisfactory results from the operation are achieved in the obsessive-compulsive neuroses and in the involutional depressions with agitation. The results in chronic alcoholism have been negligible and those in the schizophrenias are still under consideration. Prefrontal lobotomy seems to offer something of value in the relief of intractable neuroses and psychoses.

Tumors of Testicle: Report of Some Unusual Cases. M. B. Wesson.—p. 338.

Healing of Renal Tuberculosis.—Regardless of whether renal tuberculosis is secondary to some preexisting tuberculous lesion in the body, the bacilli must be conveyed to the kidneys by the blood stream and therefore Reid believes that it is illogical to assume that infection by this route is not evenly distributed and consequently bilateral. The passage of time and natural resistance may obscure the initial bilateral distribution in some cases by reason of healing in one kidney. The development of renal tuberculosis depends primarily on the degree of resistance of the organism to the infection. It does not appear to be dependent on any local abnormality in the kidney. However, it is influenced in its progress by the supervention of secondary septic infection. It is probable that obstruction and secondary infection hasten the destruction of the kidney but not necessarily of the individual. Five cases of bilateral disease are reported; in three there was evidence of tuberculosis outside the genito-urinary system, while in the remaining two tuberculosis occurred first in the epididymis and then in the kidneys. Once infection of the kidneys has occurred, development and spread of the disease is dependent primarily on the resistance of the body to tuberculosis. Thus, renal disease differs essentially in no way from other forms of systemic tuberculosis. Resistance is dependent on the patient's natural resistance, reinforced by the well recognized therapeutic measures. Of these measures constitutional treatment holds the first place. Lett has pointed out that urinary tuberculosis should be treated on the principles that apply to tuberculosis in general. His concept marks a step forward in the management of the disease in the urinary system. Whether the presence of tubercle bacilli in the kidney urine is an indication for nephrectomy is a question that requires further study. The number of bacilli in the kidney urine bears no relation to the extent of the lesion; only careful urologic survey can define how far the destruction has progressed. If operation is decided on it should be an incident in the course of constitutional treatment, which must be sufficiently prolonged to raise the patient's resistance to the highest possible level.

*Diphtheria Prophylaxis: Review of Antigens and Methods Available. J. T. Lewis.—p. 1226.

Vitamin K and Obstructive Jaundice.—The results of the use of 2-methyl-1:4-naphthoquinone as a synthetic substitute for natural vitamin K that Macfie and his associates report are striking. The preparation when given to four patients with obstructive jaundice with low prothrombin indexes raised the index in all of them within two days. In the last case the change was evident within twelve hours. It is probable that the effect was present in the other cases at this early stage but the index was not estimated sooner. The rapidity of its effect suggests that it may be particularly valuable in the treatment of postoperative bleeding in jaundice.

Diphtheria Prophylaxis.—Because of the lack of uniformity in the current processes adopted in this country for controlling diphtheria by active immunization, Lewis reports the following study: With three fortnightly doses of 1 cc. of toxin antitoxin mixture 99 per cent of 2,163 children originally Schick positive became Schick negative. Alum precipitated toxoid was given to 1,039 children, 760 of whom were originally Schick positive

and 279 were not given the Schick test previously. From eight to twelve weeks after the second injection 99 per cent of the 1,039 children were also Schick negative. The alleged tendency of alum precipitated toxoid to cause severe reactions was disproved by this study, as only forty-three of the children complained of discomfort. Thirty-five reactions were mild and occurred after the first injection of from 0.1 to 0.25 cc. of the toxoid and eight were severe, seven of which occurred after the first injection and one after the second injection. The results obtained by some workers with toxin antitoxin mixture and toxoid antitoxin flocules have varied widely, and those following the use of "one shot" alum precipitated toxoid have been so diverse as to make this method clearly untenable. All the reports of the use of two injections of alum precipitated toxoid are in accord with a consistently high Schick negative rate. Alum precipitated toxoid by two injections should have a more accredited place in immunization schemes. This method is now employed in more than 40 per cent of the studies investigated by the author.

Relief of Pain in Carcinoma of Cervix.—Two years ago Todd pointed out that two types of pain, visceral and somatic, were experienced in advanced carcinoma of the cervix uteri and that they could be differentiated clinically. The author investigated thirty-three cases: fifteen of visceral pain and eighteen of somatic. The treatment advocated was presacral neurectomy for visceral pain and intrathecal injections of absolute alcohol for somatic. When the appropriate method was used, the percentage of success was high. In the subsequent two years the author has continued this research in a further series of fifty-five cases. He now presents his observations on this second series. In investigating the cases a careful history and description of the pain is taken, a neurologic examination is made, examination under anesthesia, cystoscopy, sigmoidoscopy and exclusion of pyometra are done and roentgenography of the lumbosacral spine and pelvis and pyelography complete the investigation. Then an assessment is made of the type of pain and of the nerve path concerned. The author regards pain of sufficient severity to prevent sleep unless sedatives are administered as the most reliable indication of intractability. A week or even longer may be necessary for deciding whether the pain is minimal and the patient over-reacting to it. He is convinced that it is most important to have a precise objective phenomenon, such as interference with sleep, when attempting to assess and treat patients alleged to have severe pain. As regards visceral pain, the commonest cause is ulceration of the rectum, malignant involvement of the base of the bladder, or pyometra. As before, either direct local therapy or presacral neurectomy has almost always given relief. In cases associated with an advancing malignant process an alternative therapy to presacral neurectomy consists in injections of alcohol so administered as to

affect the upper lumbar roots, and the author thinks this will replace neurectomy in the malignant cases. Intrathecal injections of alcohol have been given in twenty-eight further cases of somatic limb pain. It could be confirmed that intrathecal injection of absolute alcohol is a valuable agent for the relief of intractable pain. The average duration of relief was three months. Two patients are still alive, having been treated over two years ago, and the relief has persisted, though in one the pain is beginning to recur. In conclusion it is stated that relief of intractable pelvic and lower limb pain associated with advanced cancer should be achieved satisfactorily in nearly 90 per cent of the cases. Failure to achieve relief probably indicates a technical imperfection or the presence of cord compression or is due to drug addiction. Changes in the nerve roots and spinal cords found at necropsy in two cases are recorded, and it is emphasized that injections of alcohol should be given only in the presence of malignant disease.

Epidemic of Apparent Influenza.—Martin and Fairbrother investigated seventy cases of apparent influenza which occurred during a mild epidemic in January and February 1939. Although in certain respects the outbreak resembled epidemic influenza, the evidence for concluding that the epidemic was not caused by the influenza virus is reasonably convincing. The virus was not isolated in typical cases by a technic which had succeeded on other occasions, and there was no increase in antibody titer of the serums of convalescent patients tested by complement fixation. The symptoms were, on the whole, uniform and simulated those of epidemics caused by the influenza virus. This tendency to uniformity suggests that probably one etiologic agent was responsible. It seems equally clear that this agent was not the influenza virus nor could a bacterial cause be demonstrated. The probability thus appears to be that the 1939 epidemic was caused by a virus which has not yet been isolated. The reactions obtained in some of the ferrets inoculated with material from such cases lends support to this view. It may be difficult clinically to differentiate cases of infection with the influenza virus from those caused by some other agent. Moreover, the high contagiousness and rapid spread of infection, even in a localized group, cannot be taken as a sure indication of the participation of the influenza virus in the outbreak. The investigation of this epidemic clearly establishes the necessity to search further for viruses other than the influenza virus which may be responsible for infections of the upper respiratory tract that occur in epidemic form and simulate clinical influenza.

Comparison of Rickettsial Strains of Ticks in Montana and Q Fever.—Burnet and Freeman find that the rickettsia isolated from ticks in Montana by Davis and Cox and from a laboratory worker by Dyer is immunologically indistinguishable from the rickettsia of Australian Q fever. The American strain, like the Australian strain, is pathogenic for guinea pigs, mice and two species of monkeys. It is of greater virulence for all three species, and if a large enough dose is administered it produces a fatal infection in guinea pigs. The authors believe that the two types should be included in the same species.

Etiology of Induratio Penis Plastica.—May directs attention to the possibility of finding a positive intradermal Frei reaction in cases of induratio penis plastica. He reviews a case presenting a sclerogenic process and lymphatic infiltrations on the dorsum of the penis, in which he first resorted to the Frei test. The reaction was positive and so the author decided to institute antigenotherapy against venereal lymphogranuloma. From the first injection the symptoms began to subside, the viscous secretion dried up quickly, the lymph nodes rapidly decreased in size and the induration of the corpus cavernosum receded slowly. The author cites additional cases observed by himself or by others. Until December 1938 he was able to collect forty-three cases; in thirty-eight of these the Frei reaction was positive and in five it was negative. He does not believe that venereal lymphogranuloma is the only etiologic factor of induratio penis plastica, which probably can be produced also by other infections. However, he thinks that venereal lymphogranuloma is the etiologic factor of induratio penis plastica in a comparable percentage of cases as it is the cause of rectal stricture.

Mercury Bichloride in Pemphigus.—In an extensive report, Sonnenberg reviews a case of pemphigus which was complicated by secondary infection. To counteract the offensive odor given off by the patient, which was probably caused by the presence of *Staphylococcus pyogenes aureus*, and because he had found intramuscular injections of mercury bichloride helpful in cases of furunculosis, he decided to resort to injections of mercury bichloride. The injections were given daily. During the first two weeks of this treatment the bullae became more transparent, the odor diminished, the skin became drier and islands of epidermis commenced to reappear. Later the patient's general condition improved; the appetite as well as the weight increased. Toward the seventh week of the application of mercury bichloride the last visible symptoms gradually disappeared. The favorable effects obtained with mercury bichloride in this case induced the author to employ it in other cases of pemphigus. Since 1932 he has used it in thirty-four cases of pemphigus; fourteen of the patients were men and twenty were women. The ages of the patients varied between 8 and 71. Chronic pemphigus vulgaris existed in twenty-four cases, pemphigus foliaceus in four and pemphigus vegetans in six. In twenty-four cases the first symptoms appeared on the mucous membranes, in ten on the skin. Ocular complications existed in twenty-two cases and enucleation of an eye became necessary in one case. Dystrophic deformations of the nails were encountered in fourteen cases. In three cases complete loss of hair was observed. The symptomatology varied considerably, although certain conditions were always found. Following a discussion of the theoretical justification of the use of salts of mercury in the treatment of pemphigus, the author raises the question as to what should be done after the termination of the acute phase of pemphigus and then describes his conception of the continuous treatment with mercury bichloride. Reports of cases in which the continuous treatment was employed indicate that the maintenance treatment with mercury bichloride consisted of one injection every week or every second week. Interruptions of these injections were followed by relapses which necessitated renewed hospitalization. In some cases the maintenance treatment was continued for several years.

Vitamin A in Treatment of Typhoid in Children.—Because patients with typhoid behave clinically like subjects with deficiency in vitamin A and because from the onset of typhoid the patients present biologic signs that accompany in-

iciency of vitamin A, Giraud and Vallette reasoned that the administration of vitamin A might be of value in patients with typhoid. They administered vitamin A to patients either in the form of cod liver oil with at least 2,000 units per cubic centimeter in doses of from ten to twenty drops a day or by utilizing an injectable solution, standardized at 3 per cent of the active products, injected intramuscularly in doses of 0.25 cc. every two days. They employed vitamin A in seventy-one cases of typhoid. They admit that the general course of the disease is not greatly changed by this medication; nevertheless, the time required for cure seems to be somewhat shorter than usual. Furthermore, the general prognosis is more favorable, because the mortality rate in the cases treated with vitamin A was only 11 per cent whereas in comparable cases treated without vitamin A it was about 20 per cent. Cardiac and cutaneous complications have been less frequent and more benign; however, pulmonary, hepatic or nervous complications apparently have not been modified. The intestinal hemorrhages have been completely averted. Thus it is certain that the vitamin A exerted a favorable effect on the nutrition of the intestinal lining. The authors recommend the systematic employment of this treatment in the course of typhoid.

Metrazol Therapy in Migraine.—Leroy reports three cases of migraine in which metrazol was successfully applied intramuscularly in doses varying, preferably, between 0.25 and 0.3 Gm. in a 10 per cent solution. One of the patients, aged 63, had suffered from migraine for fifty years. His attacks would occur every ten days together with violent headaches, vomitings and insomnia. Sixteen injections of from 0.2 to 0.3 Gm. were given during a period of four months, followed by a single injection of 0.3 Gm. about two months afterward. At the end of a further period of four and one-half months the migraine appeared only at monthly intervals in an attenuated form of light headache, sometimes accompanied with vomiting. The condition of another patient, aged 35 years, with anamnesis of migraine in the mother, dated back to only a few years. He was subject to monthly attacks, sometimes lasting two weeks, with the usual signs. A severe dietary regimen was unavailing. Four intramuscular injections of from 0.2 to 0.25 Gm. of metrazol were sufficient to cure the disease, correct constipation and normalize nutrition. The disease of the third patient, aged 42 years, also with anamnesis of migraine in the mother, had a background of neurasthenia, debility, tachycardia and marked anemia. Crises of migraine occurring once a week and increasing in violence set in, a year before treatment, with nausea and vomiting. The administration of fourteen injections usually of from 0.2 to 0.25 Gm. of metrazol progressively reduced the symptoms. Three months later the patient was feeling well and had had only one or two slight attacks. The author attributes the efficacy of metrazol in migraine to shock induced by the intramuscular administration of the drug but invites further study.

Role of Radicular Nerves in Human Tetanus.—Benedek and Juba in an earlier report described the histopathologic aspects of ten cases of tetanus. In this paper they give an account of studies in four additional cases. The presence of contusions or wounds provided the prerequisites for the invasion of the anaerobic tetanus bacilli, and symptoms like lockjaw, stiffness of the neck and rigidity of the musculature were so

pronounced in all four cases that the diagnosis could not be doubted. The histologic aspects in the first two cases were especially varied, in the third case negative and in the fourth case uncommonly extensive. In the first two cases the infiltrations of the radicular nerves, consisting chiefly of lymphocytes and leukocytes, were so considerable that in some places the connective tissue framework was completely filled by them. The radicular nerves presented the most serious changes, although in case 1 there existed an extensive and in case 2 a localized infiltration of the pia mater. There seems to exist a correlation between the duration of the disease and the histologic picture. In case 1 the disease lasted four days. The infiltrations, located in the radicular nerves and in the pia mater, were grave. In case 2, in which the disease lasted eight days, the infiltrations were less extensive, existing chiefly in the radicular nerves. In case 3, which had lasted ten days, no histologic changes were observable. All this confirms the opinion which the authors had expressed previously, that the gravity of the infiltration depends chiefly on the duration of the disease. Case 4, however, apparently is a contradiction, for in spite of its long duration (seventeen days) there remained sparse infiltrations in the fibrous sheaths of the radicular nerves and severe infiltrations in the pia mater. In all probability the infection in this case was particularly virulent. In this new series of cases, as in the earlier one, the lesions of the cells of the intervertebral ganglions were more severe than those of the motor elements of the spinal cord. The swelling of the axis cylinders of the radicular nerves was also common, while the myelin sheaths proved unimpaired in the authors' cases. They think that the infiltrations in the nervous system, particularly those in the connective tissue of the radicular nerves, are a manifestation of the increased activity of the reticulo-endothelial apparatus of the central nervous system.

*Sclerosis Tuberosa: Four Cases with Encephalography. R. Ruggeri.—p. 1040.

Sclerosis Tuberosa.—Ruggeri calls attention to the importance of sclerosis tuberosa from a pediatric point of view. He observed eight cases of the condition in institutions for children with mental deficiency. Four cases are reported. The disease was characterized by the typical symptoms (epilepsy, mental deficiency or idiocy, alterations of the skin or else leukoderma and Pringle's adenoma) in three cases. Epilepsy developed during the first months of life of the patients and it had resisted prolonged treatment with phenobarbital or bromides. The neurologic symptoms were scanty. One of the two patients who suffered from divergent strabismus showed a bilateral Babinski reflex. A patient had congenital luxation of the hip joint and valgus foot. The fourth patient showed all the typical symptoms but epilepsy. He had Pringle's adenoma and also Barlow's sebaceous adenoma of the scalp. In all four cases the blood, cerebrospinal fluid and urine were normal. The fundus of the eye was grayish during ophthalmoscopic examination in one case. Encephalography was performed in all cases. It gave normal encephalograms in two cases. In one case of the typical form it showed deformation and dilatation of the right ventricle, which was more acute when encephalography was repeated two years later. In the case presenting the atypical form of the disease encephalography showed deformation and dilatation of the lateral ventricles and the presence of growing tumors (lack of air filling) in the ventricles. The author emphasizes the importance of encephalography for the diagnosis of sclerosis tuberosa, especially in atypical forms of the disease.

*Diabetes Mellitus and the Hypophysis-Thalamencephalon System. G. Köhne.—p. 241.

Acromegaly and Nephritis: Case. K.-H. Riwooldt.—p. 255.

Diabetes Mellitus and the Hypophysis-Thalamencephalon System.—Köhne made postmortem examinations in twelve cases of diabetes. Special attention was paid to the hypophysis-thalamencephalon system. Changes were observed

in the pancreas in all cases, such as island atrophy, sclerosis, lipomatosis or inflammatory processes. In one case with acromegaly an eosinophil cell tumor of the anterior lobe of the hypophysis occurred. In one case of apparently extra-insular origin, necrosis in the anterior lobe of the hypophysis was observed. The author points out that the one sided conception of a central genesis of diabetes is too narrow and does not do justice to the complicated course of carbohydrate metabolism carried out by the synergistic action of several endocrine organs. However, this does not mean denying glycosuria of central origin. The author concludes that the cause of classic diabetes does not lie primarily in the hypophysis-thalamencephalon system.

*Treatment of Asthenic Conditions with Desoxycorticosterone Acetate. H. Eitner.—p. 1544.

Desoxycorticosterone Acetate in Asthenic Conditions.—Eitner tried desoxycorticosterone acetate in 0.5 per cent oily solution in cases of asthenia with severe emaciation. The patients were given daily one intramuscular injection of 1 cc. of the oily solution, that is, 5 mg. of the drug. The nine cases reviewed were characterized by general debility, weakness and loss of weight. The total quantities of desoxycorticosterone acetate administered in these cases varied between 0.075 and 0.26 Gm. In some cases the treatment was limited to the administration of desoxycorticosterone acetate and the resulting increase in weight was rapid and continuous. In other cases the drug was given after the insulin-dextrose therapy had produced unsatisfactory results and here again the desoxycorticosterone acetate proved effective. The increase in weight that followed treatment with desoxycorticosterone acetate was accompanied by an improvement in the general condition and in the subjective complaints. It is important that the organism receive an adequate supply of foodstuffs but forced feeding is unnecessary. The fact that the administration of the drug succeeded in cases in which the customary methods failed suggests that insufficiency of this substance existed although the characteristic symptoms of Addison's disease were absent. On the other hand, there are cases of emaciation in which desoxycorticosterone acetate fails to act in this manner. The author hopes that further investigations on the resorption of fat and dextrose may perhaps make possible a more exact indication for the use of the preparation than was possible on the basis of merely clinical observations.

Respiratory Intake of Aluminum Dust.—According to Ehrismann, aluminum which is taken in through the gastrointestinal tract is not harmful in the quantities which occur under ordinary conditions. In this report he considers the respiratory intake of aluminum dust. He describes observations on rabbits and guinea pigs, which for periods of many weeks were exposed daily for six hours to the inhalation of dust consisting of aluminum-bronze. Pathologic conditions were observed in none of these animals. It was observed that guinea pigs developed pneumonia after the inhalation of comparatively small quantities of lead oxide dust. Studies on the

quantity of aluminum in the lungs revealed that slightly larger quantities were present in the lungs of the animals exposed to the aluminum dust than in those of the controls. Further experiments will be necessary to determine whether aluminum is absorbed by the pulmonary surface and is transported to other organs, although this appears improbable. The reported observations provide further proof of the harmlessness of aluminum even if it acts in the form of a dust on the upper and deeper respiratory passages. Large quantities of dust may cause annoyance and catarrhal reactions, but severe impairments and lesions that are specific for aluminum are not to be expected.

Duration of Immunity Against Diphtheria.—Sigurjónsson reports that diphtheria, which ordinarily is comparatively rare in Reykjavik, Iceland, increased during 1935 and protective immunization was employed for the first time on a large scale. In 1939 Schick tests were made on the school children to determine what degree of protection was still in existence four years after the immunization. Children between 7 and 12 who had not been immunized gave negative Schick tests on the average in 10.4 per cent of the cases. Comparison with the preliminary tests in 1935 disclosed that the immunity among the nonimmunized is about the same as it was at that time. Of 867 children who four years ago had been given two injections of toxoid that had been precipitated with aluminum hydroxide, 66.3 per cent were still Schick negative. Eight months after the immunization 95.4 per cent were negative. Of 483 children who had been given only one injection of the same toxoid, only 19.5 per cent were now Schick negative, and of 134 who were immunized by two injections of Ramon anatoxin that had been treated with formaldehyde, 26.12 per cent were Schick negative. Eight months after the immunization 80.7 per cent of this group were negative. A transition from a Schick-negative to a Schick-positive reaction took place in the course of four years in forty-six of 181 children (25 per cent) who had received two injections of the toxoid precipitate, in sixty of eighty-eight children (62.2 per cent) who had been given two injections of anatoxin treated with formaldehyde and in fourteen of twenty-eight children (50 per cent) who had become negative by latent infection. The author concludes that in Reykjavik the Schick immunity acquired naturally by children is weak and usually is temporary. The immunity obtained by inoculation was likewise of short duration in many cases. In the presence of such immunity conditions a single immunization is not enough for an effective prophylaxis of diphtheria. The Schick test is entirely adequate for epidemiologic purposes.

*Treatment of Epidermophyton Infection with Copper Iontophoresis. O. Jersild and Marie Plesner.—p. 1475.

Treatment of Epidermophyton Infection with Copper Iontophoresis.—Jersild and Plesner discuss seventy-nine cases of this infection treated since their first report on copper iontophoresis treatment. In sixty-six cases the disease was localized to the feet, in twelve to the hands and in one to the genitalia. In most of the cases the duration had been several months, in some, years. As a rule one or two treatments were effective, and in most cases an average of from five to six treatments sufficed; in a few instances ten or twelve treatments were necessary. Sixty-nine patients were discharged completely cured, eight still presented slight desquamation on discharge, and two left before ending treatment. No after-examinations have been made because of the difficulty in distinguishing between recurrence and reinfection.

THE DIAGNOSIS AND TREATMENT OF CARDIAC EMERGENCIES

JAMES ALEXANDER LYON, M.D.
WASHINGTON, D. C.

Among the most alarming of the medical emergencies are those arising from acute conditions within the heart. Immediate treatment is frequently imperative. Fortunately, there are a half dozen drugs used in cardiac emergencies which are now available in sterile solution in single dose ampules, convenient for immediate hypodermic administration. These drugs belong in the kit of every physician. Their proper administration to achieve an optimum therapeutic effect and the emergency conditions which demand their use should be common knowledge.

CARDIAC ARRHYTHMIAS

Probably in no cardiac emergency does death seem more instantly impending than in the Adams-Stokes syndrome. If the ventricles cease to pulsate for as long as eight or ten seconds, cerebral anemia results and the patient suddenly loses consciousness. If the ventricles remain in diastole for more than fifteen seconds, the Adams-Stokes syndrome appears with convulsive seizures accompanying the syncope. The ventricular standstill, if untreated, may continue until sudden death occurs. The diagnosis is not difficult when the patient is seen in an attack. The abnormally slow heart rate, or the absence of the apex beat, and the rapid venous pulsations in the neck due to the uninterrupted auricular action, distinguish it. The syndrome may appear at the onset of complete heart block or when there is a sudden change from partial to complete heart block. It appears occasionally in acute coronary thrombosis when the infarction involves the conduction system. Two such cases have recently come under my observation, one ending fatally.

As an emergency measure in the treatment of a prolonged attack of ventricular standstill, epinephrine hydrochloride (adrenalin chloride) should be injected directly into the heart. A $2\frac{1}{2}$ inch (6 cm.) 22 gage needle may be inserted into the fourth left interspace about 2.5 cm. from the sternal border. From 0.5 to 1.5 cc. of a 1:1,000 solution of epinephrine hydrochloride may then be injected into the ventricular wall or cavity. There is some dispute as to whether it is desirable to inject the drug into the region of the sino-auricular node. During the less severe attacks of convulsive syncope or when the attacks are recurring, from 0.25 to 1 cc. of a 1:1,000 solution of epinephrine

should be injected subcutaneously every few hours for as long as is necessary to maintain a heart rate of over 30 beats per minute. The drug stimulates ventricular irritability and shortens the period of diastole. It has an immediate, but not a prolonged, effect. Ephedrine, barium chloride and atropine sulfate have been used to control Adams-Stokes seizures, but they have not produced as uniform results as has epinephrine.

A rapid ventricular rate, approaching 200 beats per minute, if prolonged, will at times induce alarming symptoms in persons without organic heart disease. Palpitation, dyspnea, vertigo, syncope and severe precordial pain may result. When a rapid ventricular rate is superimposed on organic heart disease such as mitral stenosis or aortic regurgitation, acute congestive heart failure may supervene and if the ventricular rate is not decreased it may cause death.

If the rapid beating of the ventricles is due to paroxysmal auricular tachycardia originating in the sinus node, the attack may occasionally be terminated by vagus pressure. If this procedure does not immediately reduce the ventricular rate, acetyl-beta-methylcholine hydrochloride (mecholy) should be administered subcutaneously. The optimum dosage varies with the age and weight of the patients, one-sixth to one-third grain (0.01 to 0.02 Gm.) being sufficient for young or light weight patients and one-half to 1 grain (0.03 to 0.06 Gm.) being necessary for elderly or obese persons. In a majority of cases the heart will resume its normal rate within fifteen minutes. If it does not do so within two minutes, the site of the injection may be massaged to hasten absorption. If this is not effective, carotid pressure may be applied while the drug is still active.¹ If the initial dose does not check the rate, a second dose may be administered after the lapse of twenty or thirty minutes. Because the drug produces marked stimulation of the parasympathetic nerves, the patient, to avoid fainting, should be lying down during and immediately after the injection. Disagreeable symptoms such as flushing, salivation, profuse perspiration, nausea, vomiting and occasionally dyspnea, precordial pain or collapse may accompany the action of the drug. These symptoms, if alarming, can be instantly checked by the intravenous administration of atropine sulfate $\frac{1}{100}$ grain (0.0006 Gm.). The use of the drug is contraindicated in cases of bronchial asthma and in cases of arteriosclerosis with hypotension, angina pectoris or recently healed myocardial infarction. It is usually not effective in cases of tachycardia in which the rapid ventricular action is produced by ectopic stimuli.

In all cases of paroxysmal ventricular tachycardia as well as in those cases of paroxysmal auricular tachycardia in which mecholy is either contraindicated

From the Department of Clinical Medicine, Georgetown University School of Medicine.

Read at the annual meeting of the American Therapeutic Society, St. Louis, May 13, 1939.

1. Starr, Isaac, Jr.: Acetyl- β -Methylcholine: IV. Further Studies of Its Action in Paroxysmal Tachycardia and in Certain Other Disturbances of Cardiac Rhythm, *Am. J. M. Sc.* 191: 210-224 (Feb.) 1936.

or not effective, quinidine sulfate should be given orally, from 3 to 6 grains (0.2 to 0.4 Gm.) every two hours for six or more doses. I have frequently given up to 45 grains (3 Gm.) of quinidine sulfate during a twenty-four hour period without its having produced untoward effects. However, when massive doses of this drug are to be used it must be fully understood that the patient should first be tested for quinidine idiosyncrasy. If the drug is tolerated, the patient should remain under observation, at rest in bed, during the course of treatment. Electrocardiograms should be taken at intervals in order to note any toxic effect of the quinidine appearing in a prolongation of the conduction time, which would call for the discontinuance of the drug.

In the treatment of paroxysmal auricular fibrillation the use of quinidine sulfate is specifically indicated. Quinidine, unlike meclolyl, does not slow the heart rate by a vagal effect but acts directly on the heart muscle, decreasing its irritability and conductivity and prolonging the period of diastole. Its administration is contraindicated in cases of long standing or permanent auricular fibrillation because of the possibility that with the restoration of normal auricular pulsation portions of mural thrombi might be detached and be carried into the circulation. When the ventricular rate is accelerated in a case of chronic auricular fibrillation, digitalis should be administered in sufficient amounts to slow the rate.

In paroxysmal auricular flutter, digitalis therapy will change the flutter to auricular fibrillation in about 50 per cent of the cases. The withdrawal of the digitalis may then be followed by a spontaneous cessation of the fibrillation. If this procedure is not successful, the administration of quinidine sulfate may restore a normal rhythm.

DIGITALIS

The most generally accepted method of digitalis therapy is the oral administration of standardized powdered digitalis leaves in tablets of $1\frac{1}{2}$ grains (0.1 Gm.). As to the value of using digitalis preparations other than the standardized powdered leaf, I am in hearty agreement with Christian's² statement: "Tincture of digitalis may be substituted in mouth dosage for the powdered leaves if for any reason that seems desirable; rarely, however, in my experience is that the case; if for no other reason, the convenience of pills and capsules would give a preference to powdered leaves over the tincture; however, it has always seemed to me that the whole leaf has a therapeutic superiority to the alcohol soluble portions present in the tincture. . . . At present there is no advantage to be obtained by using any other than Pharmacopeial preparations of digitalis, notwithstanding the many proprietary digitalis preparations that are being offered with great enthusiasm to the medical profession, their dispensers making many claims for their superiority, claims that seem not justified as far as my own clinical experience goes."

The dosage which will secure the digitalization of a patient and thereby produce a therapeutic effect may be roughly computed on the basis of the patient's weight. Provided the patient has not received digitalis within the previous two weeks, the dosage should approximate $1\frac{1}{2}$ grains for every 10 pounds (4.5 Kg.) of body weight, plus $1\frac{1}{2}$ grains for each day during the period of digitalization. That is, if a patient who weighs

150 pounds (68 Kg.) is to be digitalized over a two day period he will receive approximately 25 grains (from 20 to 30 grains [$1\frac{1}{2}$ to 2 Gm.]). From 12 to 15 grains (0.8 to 1 Gm.) may be given in divided doses at six or eight hour intervals during the first twenty-four hours and the remainder in divided doses during the subsequent twenty-four hours. If the need for rapid digitalization is urgent and the patient has not received digitalis within the previous two weeks, he may be given as much as $7\frac{1}{2}$ grains (0.5 Gm.) at four hour intervals for two or three doses, followed by 3 grains (0.2 Gm.) at eight hour intervals until the requisite dose has been given. It should be borne in mind, however, that such massive doses of digitalis and rapid digitalization of a patient as have just been outlined are to be resorted to only in emergency cases and then only when the patient can be kept under close observation. In all other cases digitalization should proceed more slowly and cautiously.

The computation of the dosage by body weight is only an approximation. Relatively more digitalis should be given to children, to light weight adults and to patients with a marked degree of decompensation. Children in particular require fairly large doses of the drug to obtain a therapeutic effect. Patients of advanced years usually require less digitalis than their weight would indicate. When edema is present, its added weight should not be included in the body weight on which the digitalis dosage is computed; instead, the patient's average weight for the year prior to the onset of the edema may be taken as a basis.

As a patient is not fully digitalized until a state of saturation has been reached, the dosage in emergency cases should be sufficient to produce either a therapeutic effect or early evidence of approaching toxicity. The drug should not be withdrawn, however, solely because of a single spell of vomiting or headache. In cases of congestive heart failure, vomiting may be due to congestion of the gastric mucosa and therefore be a manifestation of the cardiac failure, rather than of the toxicity arising from the action of the drug. If vomiting prevents the oral administration of digitalis, equivalent amounts of the drug in solution may be given intravenously until it is tolerated by the oral route.

In order to maintain a patient in a state of therapeutic digitalization it is necessary that he receive daily an amount of the drug equivalent to that which he excretes. This is generally about $1\frac{1}{2}$ grains daily. If this dose is not effective in slowing the heart rate in a case of rapid ventricular action or in improving the circulation in a case of congestive heart failure, 3 grains may be given every other day and $1\frac{1}{2}$ grains on the alternate days. In rare cases it may be necessary to give 3 grains daily until the heart becomes compensated. It is important that the particular maintenance dose which will achieve the optimum therapeutic effect be determined for each individual patient by both clinical and electrocardiographic observations.

In the presence of a toxic state arising from the overdigitalization of the patient, there will usually be manifested clinically a slowing of the heart to a rate of 60 beats per minute or less, and the appearance of premature contractions producing a coupling of the beats, heard on auscultation. Certain gastrointestinal, ocular and neurologic symptoms may also appear such as nausea, vomiting, dimness of vision, inability to focus the eyes, restlessness and disorientation. The electro-

2. Christian, Henry A.: *Drug Treatment of Cardiac Decompensation*, J. A. M. A. 108:44-46 (Jan. 2) 1937.

cardiogram will show an exaggeration of the T wave deflection associated with a "digitalis effect"; a prolongation of the PR interval, indicating an auricular-ventricular block; premature ventricular beats occurring in couplets (bigeminy), and, in grave toxic states, the appearance of ventricular paroxysmal tachycardia. It is because the electrocardiogram shows definite evidences of the approach of a state of digitalis intoxication of the myocardium that the administration of the drug should be controlled by frequent electrocardiographic readings. When clinical or electrocardiographic signs of overdigitalization appear, the drug should be withheld for a day or two and its administration resumed in decreased dosage.

Digitalis acts directly on the heart, (1) depressing the function of the sino-auricular and auriculoventricular nodes, (2) contracting the muscle fibers, (3) decreasing the size of the chamber walls, (4) lessening auricular and ventricular irritability, (5) prolonging diastole and (6) increasing the force of systole.³ The clinical results of digitalis therapy are usually manifested in a slowing of the heart rate and in a general improvement of the circulation. In cases of failing or dilated hearts the administration of digitalis frequently results in an increase of the cardiac output and the relief of venous congestion. Occasionally, however, fibrosis of the myocardium is so extensive that digitalis cannot restore compensation. When hyperthyroidism is the underlying cause of cardiac dilatation and failure or of a rapid ventricular rate, the results of digitalis therapy will be disappointing until the thyroid condition has received appropriate treatment.

CONGESTIVE HEART FAILURE

Acute congestive heart failure is one of the most commonly seen conditions demanding emergency treatment. Cases of organic heart disease such as valvular incompetency and stenosis may remain compensated under a normal regimen; but when the burden of infection, fatigue, excitement, prolonged nervous strain or a rapid ventricular rate is added, congestive heart failure may suddenly appear. If the precipitating factor is not removed, the attack of failure may develop rapidly into an emergency.

In left ventricular failure, dyspnea, orthopnea and air hunger appear and increase in severity with the degree of failure. The associated pulmonary congestion may give rise to a productive cough and to hemoptysis. Patients with failure of the left side of the heart are subject to alarming and not infrequently fatal attacks of acute paroxysmal dyspnea. The attacks, which are usually nocturnal, are marked by extreme dyspnea and a cough which is productive of profuse frothy blood-tinged sputum. The blood pressure is at first elevated but later falls. As the pulmonary edema becomes acute, circulatory collapse occurs accompanied by pallor and cyanosis, marked perspiration and a rapid feeble radial pulse. If treatment is delayed, death may ensue. The most important emergency measure is the subcutaneous administration of morphine sulfate, one-fourth grain (0.015 Gm.), repeated in fifteen minutes if relief has not been obtained. If the morphine is not effective in

abolishing the attack aminophyllin (theophylline with ethylenediamine), $\frac{1}{100}$ grain in 20 cc. of physiologic solution of sodium chloride, should be administered intravenously, slowly during a five minute period. Clinical studies have shown that the drug causes a decline in the intrathecal and venous pressures with a subsequent diminishing of the dyspnea.⁴ Oxygen when available should be administered promptly. Phlebotomy of from 300 to 500 cc. of venous blood is frequently followed by striking improvement. As to the use of digitalis in acute paroxysmal dyspnea, Wolferth⁵ has recently expressed an opinion which I have long held on the ineffectiveness of digitalis therapy in an acute emergency condition. He states: "I find that many physicians in treating attacks of paroxysmal cardiac dyspnea are apt to give hypodermic injections of digitalis. The dosage usually employed ranges from $1\frac{1}{2}$ to 3 grains. Although . . . digitalis is often useful as a preventive measure it must be given in therapeutically effective dosage. I object to its use during an attack for the following reasons: (1) The dosage is usually too small to be effective; (2) even though enough be given, its action is too slow to combat an emergency, and (3) the use of digitalis may divert attention from more effective measures that should be employed."

When right ventricular failure is predominant there are dyspnea, marked fatigue, gastric and abdominal flatulence, nausea, venous engorgement, enlargement and tenderness of the liver, ascites, edema of the extremities and at times anasarca and hydrothorax. When a rapid elimination of the edema is necessary salyrgan, 1 cc. of a 10 per cent solution, should be injected intravenously, with or without the oral administration of ammonium chloride, $22\frac{1}{2}$ grains (1.5 Gm.) four times daily, in enteric coated capsules of $7\frac{1}{2}$ grains. The initial dose of salyrgan may be repeated after the lapse of from two to three days, when, if needed, the dose may be doubled. If large accumulations of transudates are present in the thoracic or peritoneal cavities, it may be necessary to give the patient prompt relief by aspirating the fluid, in which case a thoracentesis or an abdominal paracentesis should be carried out. The Karel diet should be instituted at once. Oxygen should be administered as an emergency measure, and morphine sulfate should be given freely to relieve the patient of dyspnea and nervousness. The slow intravenous administration of from 50 to 100 cc. of a hypertonic solution of dextrose, of 50 per cent concentration, has value in some cases in that it aids the failing heart muscle in replenishing lost glycogen. Absolute bed rest should be maintained. Patients, even children, find an upright or semirecumbent position more comfortable than recumbency, as pressure from the engorged liver is less distressing. The use of a cardiac bed, when available, is of value.

In extreme cases of failure involving either the left or the right side or both sides of the heart when the circulation is gravely embarrassed, the patient must be given immediate relief. Strophanthin should be administered intravenously, $\frac{1}{100}$ grain, provided the patient has not been properly digitalized as evidenced by an electrocardiogram. If the patient has been taking small doses of digitalis during the preceding fourteen days,

the dose of strophanthin must be regulated accordingly. Strophanthin exerts an action on the heart similar to that produced by digitalis; but, unlike digitalis leaves, it acts almost at once. Its full effect is produced in about one hour and is prolonged for from twelve to twenty-four hours. The initial dose of strophanthin may be followed by two subsequent doses at intervals of from eight to twelve hours. When possible an electrocardiogram should be taken to determine the degree of digitalis effect. After the acute stage has subsided the patient may be put on the oral administration of powdered digitalis leaves.

The edema of nephritic origin is sometimes confused with the edema arising from cardiac conditions. Within the month three patients with marked edema have come under my observation. All three patients had had prolonged digitalis therapy with no abatement of their symptoms. A carefully taken history and laboratory tests showed glomerulonephritis to be the underlying disease in each case. One patient had been taking bromides for months and had marked bromide dermatitis complicated by multiple ulcerations of the lower extremities.

A discussion of congestive heart failure should not be closed, I believe, without making clear the distinction between cardiac failure and a failure of the peripheral circulation. Peripheral failure produces the symptoms and signs of collapse and shock, including pallor, perspiration, cold clammy skin, weak heart sounds, rapid thready pulse and low blood pressure. These phenomena are seen occasionally in surgical cases, in severe hemorrhage, in dehydration, in coronary thrombosis, in arterial embolism and in other conditions which for any reason produce a sudden decrease in the volume of the circulating blood or a sudden collapse of the vascular bed. In certain of these cases the heart itself may be entirely normal in its capacity to function properly, but the vascular system fails to return a normal volume of blood to the heart.

CIRCULATORY FAILURE

The circulatory type of failure may require either of two kinds of treatment, depending on the factor which has produced the collapse. If a sudden decrease in the blood volume from hemorrhage or dehydration has been the precipitating factor, a transfusion of whole blood or the intravenous administration of small doses of 20 per cent dextrose solution or of salt solution is beneficial. If, however, depression of the central nervous system has been a contributing factor in the production of the shock through loss of vascular tone, drugs which act on the central nervous system should be administered, such as hot coffee, brandy, strychnine sulfate, one-sixtieth to one-fortieth grain (0.001 to 0.0015 Gm.) subcutaneously, or caffeine with sodium benzoate, 7½ to 15 grains subcutaneously, or intravenously if a more prompt response is desired. These drugs, as well as nikethamide (coramine), metrazol, theobromine, camphor and aminophyllin, have at times been regarded as cardiac stimulants, but it is now generally accepted that their value lies in the effect which they produce on the peripheral vascular system or on the respiratory center, secondarily to a primary effect on the central nervous system. White⁶ has pointed out that although caffeine has an important stimulating effect on the nervous system and vasomotor center and

nikethamide and aminophyllin often stimulate and regulate a depressed respiratory center, they are not known to have a direct effect on the action of the myocardium. None of these drugs, therefore, should be substituted for digitalis in the treatment of congestive heart failure. Digitalis, however, is not known to exert a direct effect on the vascular system and therefore should not be administered in circulatory failure. It should be clearly understood by surgeons as well as by clinicians that digitalis therapy not only has no value in collapse or surgical shock but may even do harm in that it slows the heart rate. Much of the confusion concerning the results of digitalis therapy in coronary thrombosis has, I believe, come from an attempt to institute digitalization while vascular collapse was a predominant factor in the clinical picture. In the presence of shock associated with low venous pressure the use of digitalis is contraindicated.

CORONARY THROMBOSIS

The syndrome of acute coronary thrombosis is too well known to be discussed in detail. If pain is present, its continued intensity and prolonged duration and the ineffectiveness of the nitrites to control it, will differentiate it from the pain of angina pectoris. Pain may be absent in coronary thrombosis, and intense dyspnea may be the striking symptom. Peripheral vascular failure with signs and symptoms of collapse and shock may be present without pain or dyspnea. On even a tentative diagnosis of coronary occlusion, the patient should be put at complete rest in bed. If within twenty-four or thirty-six hours signs of infarction appear, such as a rise in temperature, an elevation of the leukocyte count and a pericardial friction rub, the patient should remain at rest for several weeks. The important drug in the emergency treatment of acute coronary thrombosis is morphine sulfate, which should be given promptly and in sufficient amounts to quiet the patient and to relieve him of pain. From one fourth to one half grain may be given subcutaneously and the dose repeated if necessary. If there is cyanosis, rapid heart action, dyspnea, orthopnea or other signs of myocardial anoxemia, oxygen in concentrations of from 50 to 80 per cent should be administered by means of a tent. When dyspnea is persistent or when vomiting is producing dehydration, the intravenous administration of a hypertonic solution of dextrose, from 50 to 100 cc. of a 50 per cent solution, should be carried out slowly and cautiously and repeated once or twice daily as needed. Caffeine with sodium benzoate, 7½ grains, may be given intravenously if there is circulatory collapse or shock. The intracardiac or subcutaneous injection of epinephrine should be resorted to in the rare instances in which the Adams-Stokes syndrome complicates coronary occlusion. Quinidine sulfate should be given orally when there is a rapid ventricular rate, but the drug should be administered guardedly. The use of mecholyl is contraindicated in the presence of coronary disease. Digitalis therapy has no place in the treatment of coronary thrombosis, except when auricular flutter or chronic auricular fibrillation is present with a rapid ventricular rate or when congestive heart failure has supervened. It should be borne in mind that massive doses of digitalis are not well tolerated during the healing stage of myocardial infarction. It should also be borne in mind that in an occasional heart there are extensive areas of coronary sclerosis, myocardial degeneration and massive infarction which leave no cardiac muscle for drugs to act on.

PERICARDITIS

A cardiac emergency occasionally arises in cases of acute pericarditis when a rapid accumulation of fluid in the pericardial sac causes marked cardiac compression. The forms of acute pericarditis in which effusions may accumulate in sufficient amounts to impede the action of the heart are (1) purulent pericarditis, secondary to a pyogenic infection such as empyema, pneumonia, an intrathoracic abscess or septicemia; (2) fibrinous pericarditis, associated with the rheumatic and other nonpurulent infections, and (3) tuberculous pericarditis, seen only when tuberculosis is present elsewhere in the body. As the cardiac compression develops, the force of the ventricular contractions is diminished and signs of circulatory embarrassment appear. The venous pressure increases and the veins of the neck appear dilated and engorged. The arterial pressure falls and the pulse volume is diminished. The heart sounds become distant and faint. The area of cardiac dullness is increased, usually to the right and to the left. A roentgenogram of the heart will show a globular contour with a bulging of both lower angles. Extensive pericardial effusion of rheumatic origin frequently gives rise to dyspnea, orthopnea, cyanosis and precordial pain. Ewart's sign, due to compression of the left lung, may appear at the angle of the left scapula as dullness, bronchial breathing and bronchophony. A to and fro friction rub may sometimes be heard over the base of the heart. A rapidly accumulating pericardial effusion is generally accompanied by an exacerbation of the symptoms of the primary infection.

Treatment should be directed both to the relief of the cardiac compression and to the control of the underlying condition, whatever the infection may be which is responsible for the acute pericarditis. If pain is present and severe, morphine sulfate from one-eighth to one-fourth grain (0.008 to 0.016 Gm.) should be administered subcutaneously. If the pain is not severe, codeine, the salicylates or the bromides may be given. When pericardial effusion is accompanied by marked circulatory embarrassment, pericardiocentesis promptly carried out may be a life-saving measure. The aspiration of even a relatively small amount of the fluid will often relieve the patient of his distress.

A favorable site for the puncture is in the fifth interspace at a point 1 or 2 cm. within the left border of cardiac dullness, as determined by percussion or by a roentgenogram. Local anesthesia of the site is desirable. An aspirating needle of medium caliber is inserted backward and inward, slowly penetrating to a depth of from 3 to 5 cm., with suction applied frequently to obtain fluid. If no fluid can be aspirated, the needle should be tilted at various angles, partially withdrawn, or completely withdrawn and inserted elsewhere. In children or young adults a safe and convenient site for the puncture is the left posterior part of the chest wall in the seventh or eighth interspace at a point in the midscapular line. The patient's left arm should be raised. The needle will have to be inserted to a depth of from 5 to 8 cm. It is usually not necessary to repeat the pericardiocentesis. Occasionally, however, with rheumatic patients the fluid must be aspirated every few days for a limited period and with tuberculous patients every week or two for a much longer time.

During pericardiocentesis of a patient with purulent effusion it is sometimes necessary, if the pus is thick,

to substitute a trocar or a needle of larger caliber for the aspirating needle with which the procedure was begun. When pus is discovered during the course of a pericardiocentesis, it is imperative that the surgical procedure of pericardiotomy be instituted at once and that the pericardium be drained at its base. As recovery depends on instituting drainage early in the course of purulent pericarditis, an exploratory pericardiocentesis should be carried out when pericardial effusion is suspected in cases of pyogenic infections. However, before these measures are resorted to in cases in which cardiac compression has not yet developed and the infectious process is largely restricted to the pericardium, sodium cacodylate from 5 to 8 grains (0.3 to 0.5 Gm.) in sterile solution should be injected intravenously. This dose with an additional 2 or 3 grains (0.1 or 0.2 Gm.) a day should be repeated daily for three or four successive days. If a definite cessation or subsidence of the effusion does not occur, a pericardiocentesis should then be resorted to.

In cases of pericardial effusion arising from a non-pyogenic infection, when the circulation is not gravely embarrassed, a delay of thirty-six or forty-eight hours will in many instances show a spontaneous subsidence of the effusion coincidental with an abatement of the underlying infection. This spontaneous improvement is frequently seen in cases of rheumatic pericarditis. Pericardiocentesis in these cases should therefore be restricted to those patients whose cardiac compression has resulted in marked circulatory embarrassment.

EMBOLISM

The emergencies arising from arterial embolism within the systemic circulation are inextricably related to cardiac conditions, as the formation of the emboli occurs in the chambers of the heart. Two predisposing factors in related sequence usually contribute to the presence of systemic arterial emboli. The first is a slowing of the blood stream within the heart chambers, due to mitral stenosis, long standing auricular fibrillation, or dilatation and functional failure of the myocardium. The resulting stasis favors the formation of mural thrombi. The second contributing factor is the subsequent restoration of normal rhythm or myocardial function, which results in more forcible contractions of the chamber walls, a breaking up of the mural thrombi and the expulsion of the detached portions into the systemic circulation. The ultimate destination of the emboli, according to clinical experience, will be lodgment within the spleen, kidneys or other parenchymal viscera, within the brain, the intestinal walls or the myocardium through the coronary circulation, or in the arteries of the extremities.

Pulmonary emboli may arise in either of two ways. They may be detached from mural thrombi within the right auricle or ventricle, whence they will inevitably be propelled into the pulmonary circuit unless there exists a congenital patency of the auricular or ventricular septum, in which case they may enter the left side of the heart and subsequently the systemic circulation. However, in the majority of cases pulmonary emboli originate in thrombosed veins, usually the larger veins of the thigh or pelvis, which often are apparently free from evidences of concomitant phlebitis. It is thought that three factors play a part in the formation of a thrombus within a vein: (1) damage to the vas-

cular wall, (2) an increase in the coagulability of the blood and (3) a decrease in the velocity of the venous blood flow. Pulmonary embolism is not infrequent in cases of heart failure and of chronic invalidism among the older age groups when venous pressure and prolonged circulation time are present. It also occurs as a postoperative or puerperal accident.

Embolic deposits within the parenchymal organs cause areas of infarction. The spleen, kidneys and lungs tolerate one or more infarctions if they are not massive, and a restitution of approximately normal function not uncommonly occurs. The brain, if vital regions are not involved, will also tolerate small areas of infarction. In the emergency treatment of embolic deposits in the parenchymal organs, absolute rest in bed and the complete relief of pain are of prime importance. Morphine sulfate from one-fourth to one-half grain should be given subcutaneously and repeated if necessary. In pulmonary infarction the patient should be placed in an oxygen tent. Supplying him with an adequate amount of oxygen not only will lessen the strain on the circulation but will add materially to his comfort and will ease difficult respiration. Shock and collapse, which invariably accompany all forms of massive arterial occlusion and multiple embolic deposits, should receive appropriate therapy, as previously outlined in the discussion of the treatment of peripheral vascular failure.

Embolic occlusion of the arteries of the extremities and of the intestine results in the development of gangrene. It is in these cases that early diagnosis and prompt surgical intervention are of the utmost importance in saving the patient's life. When embolic occlusion involves the extremities there is frequently an associated spasm of contiguous arteries. If untreated, the spasm may extend the area of gangrene. The intravenous injection of papaverine hydrochloride one-half grain will frequently abolish the associated spasm. The extremity which is affected should be kept warm but should not have direct heat applied to it. When only a small artery is involved, the development of a collateral circulation may prevent the development of gangrene. Unfortunately, subsequent emboli frequently appear in the circulation to further endanger the life of the patient.

SUMMARY

In the treatment of the cardiac emergencies, the time element is often of inestimable importance. The proper drug if administered promptly will frequently give immediate relief and may in some cases be a means of saving the patient's life. It is advisable for every physician when confronted by a cardiac emergency to have certain drugs available for instant use.

1801 Eye Street N.W.

The Spirit of Aesculapius.—The progress of medicine has ever been from the temple to the medical school. Though the statue of Aesculapius was carried from Epidaurus to Tiber Island, it was something more important that Rahere brought from Tiber Island to England; it was the spirit of Aesculapius opening the path to the medical school. Man is always too ready to mistake the symbol for the reality; the stone on which the laws are graven is apt to become more sacred than the laws themselves; but the statue of Aesculapius is unavailing if the spirit dies.—Langdon-Brown, Sir Walter: *Thus We Are Men*, New York, Longmans, Green & Co., 1939.

PUERPERAL INFECTION WITH VEGETATIVE ENDOCARDITIS

REPORT OF SULFANILAMIDE THERAPY IN TWO FATAL CASES DUE TO STREPTOCOCCUS HAEMOLYTICUS GROUPS B AND C

ALEXANDER H. ROSENTHAL, M.D.

AND

FLORENCE M. STONE, PH.D.

BROOKLYN

During a recent study of sulfanilamide therapy in puerperal infection¹ two cases of endocarditis due to *Streptococcus haemolyticus* groups B and C, respectively, were encountered. Since fatal infection due to group B is infrequent and has not been previously reported in the case of group C, report of these cases should be of interest.

REPORT OF CASES

CASE 1.—B. R., an Italian housewife aged 28, was admitted August 29, 1938, to the service of Dr. Charles A. Gordon at the Kings County Hospital. Her last menses occurred June 26. Two months later she suffered from backache and passed clots of blood by vagina. Within an hour she had a chill, followed by fever. Vaginal examination showed a sanguinopurulent discharge, a soft cervix which admitted the finger tip and a soft, tender uterus the size of a three months pregnancy. The leukocyte count was 20,000 with 87 per cent polymorphonuclears; the hemoglobin content was 80 per cent and red cell count 4,100,000. A diagnosis of septic abortion was made.

Removal of possible retained secundines was not undertaken because of the severe uterine infection. On September 4, although the fever had abated somewhat, sulfanilamide therapy was instituted. During the next four days a total of 320 grains (21 Gm.) was given. Chemotherapy was discontinued when it was found that the hemoglobin had fallen to 45 per cent and the red cell count to 2,200,000. The temperature during the following week was septic in type, rising to 105.4 F. and falling to 99.6 F. intermittently, as shown in the chart. The patient was surprisingly free from subjective symptoms. Vaginal bleeding of moderate amount occurred almost daily. Transfusions of blood were given every second or third day. In spite of the large quantity of blood (4,275 cc.) which the patient received, the hemoglobin never rose above 58 per cent.

Four blood cultures taken during the three weeks after admission were positive for *Streptococcus haemolyticus* group C. The source of the bacteremia was thought to be pelvic thrombophlebitis. After the report of the first positive blood culture on September 11, sulfanilamide was again administered. Massive doses were now given, and within ten days the patient received 890 grains (58 Gm.). In spite of the intensive chemotherapy, the patient grew progressively worse.

On the twenty-first day after admission a rough systolic murmur was heard at the apex, and the spleen was enlarged. Bacterial endocarditis was now suspected. September 29 the patient complained of sudden pain in the lower part of the back and in both legs and died shortly afterward.

Necropsy was performed by Dr. Casper C. Burn. About 500 cc. of straw-colored fluid was found in the right pleural cavity and 300 cc. in the left pleural cavity, and about 50 cc. in the peritoneal cavity.

The heart weighed 270 Gm. The epicardial surfaces were smooth and glistening. The mitral valve was the seat of a large friable vegetation. One of the leaflets had been destroyed by an ulcerative process; here the chordae tendineae were ruptured and detached. The greater part of the free border of the valve was involved in the necrotizing process. The remaining portion of the valve showed no evidence of old or chronic endocarditis.

From the Department of Obstetrics and Gynecology, Long Island College of Medicine Division, Kings County Hospital, and the Department of Pathology, Hoagland Laboratory, Long Island College of Medicine. 1. Gordon, C. A., and Rosenthal, A. H.: Sulfanilamide Therapy in Severe Puerperal Infection, *Surg., Gynec. & Obst.* 69: 631 (Nov.) 1937.

as it was thin and velamentous. The other valves appeared normal. On microscopic examination small abscesses were found throughout the myocardium.

The spleen weighed 300 Gm. and contained a large anemic infarct. A small infarct was present in one kidney. A large white saddle embolus was lodged at the bifurcation of the aorta, completely occluding the lumen. The iliac arteries were collapsed and bloodless.

The uterus was slightly enlarged; the fundus was globoid and contained a large polyp-like mass of placental tissue, covered with a yellowish necrotic exudate which extended into the myometrium. The remaining endometrium was dull, gray and covered with exudate.

The streptococcus recovered in the blood culture was identified serologically as group C.^{1a} Following the procedure of Lancefield,² the hydrochloric acid extract (tenth-molar) of a broth culture was neutralized to litmus and then centrifuged; the clear supernatant fluid was tested against antisera to streptococcus groups A to H inclusive. A clearcut precipitin reaction was obtained with group C antiserum.

Although no evidence of pelvic thrombophlebitis was found on gross or microscopic examination, it is probable that the retained infected placental tissue was the source for the invasion of the blood stream by the streptococcus, with subsequent development of endocarditis and persistent bacteremia.

CASE 2.—C. H., a Negro woman aged 24, was first observed in the obstetric clinic. A history of rheumatic fever with cardiac involvement during childhood was obtained. She had had four previous deliveries. The first two pregnancies and labors were uncomplicated save that she went into premature

Temperature curve in case 1 showing the septic clinical course of the patient and the sulfanilamide therapy.

labor at seven months and delivered infants weighing 5 pounds (2.3 Kg.) each. During her third pregnancy she suffered what appeared to be a beginning attack of cardiac decompensation with arrhythmia, but subsequently she was delivered without cardiac symptoms. The fourth pregnancy and labor were uncomplicated. The last menstrual period was on May 15, 1938. The patient had complained of dyspnea and orthopnea since the second month of pregnancy.

Examination revealed an enlarged heart with presystolic and systolic apical murmurs. X-ray examination of the chest showed a globular heart. A diagnosis of rheumatic heart disease with mitral stenosis and insufficiency was made. During the remainder of her pregnancy the patient suffered headaches, spots before her eyes, edema and a rise in blood pressure to 140 systolic, 84 diastolic.

The patient was admitted to the service of Dr. Charles A. Gordon Jan. 11, 1939, and was delivered spontaneously the next day of a 7½ pound (3.4 Kg.) fetus with use of local anesthesia. There was no change in her cardiac status during labor. Her immediate postpartum course was uneventful. On the fifth day post partum there was a rise in temperature to 104 F. with a rise in pulse rate. The blood count was normal and the patient felt well. However, both blood and uterine cultures were positive for *Streptococcus haemolyticus* group B. She was given a blood transfusion of 250 cc. and received 20 grains (1.3 Gm.) of sulfanilamide every four hours.

The patient continued to have a septic type of fever but otherwise appeared well. Sulfanilamide therapy was discontinued on

the twelfth day post partum because of headache. At this time her condition was improved and the blood culture was negative. The sulfanilamide titer reached its highest level of 12 mg. after 820 grains (53 Gm.) had been given over a period of seven days. On the sixteenth day post partum she had a chill and a rise in temperature to 104 F. A blood transfusion of 250 cc. was given and sulfanilamide therapy was resumed. A septic type of fever with but few other symptoms continued thereafter.

Four blood cultures taken over a period of six days were negative. February 4, however, hemolytic streptococci were found and subsequent cultures were consistently positive for this organism. Sulfanilamide therapy was again stopped on the twenty-sixth day post partum. By this time a total of 2,250 grains (146 Gm.) had been given.

On the thirty-second day post partum a change in the cardiac status of the patient was noted. The apex was beating violently; the murmurs had changed in quality and were now heard over the entire chest. A diagnosis of acute bacterial endocarditis was made. Petechiae were not seen in the conjunctivas until nine days later. Blood and uterine cultures continued to be positive for the hemolytic streptococcus.

On the forty-third day post partum the patient was started on sulfapyridine therapy and received a total of 247 grains (16 Gm.) in three days. On the day after this medication was instituted clinical signs of a cerebral embolism appeared, and two days later she died.

Necropsy was performed by Dr. Casper C. Burn. Several small petechiae with white centers were noted in the conjunctivas. One hundred and fifty cc. of clear straw-colored fluid was found in the left pleural cavity and 75 cc. in the right. Many petechial and purpuric hemorrhages were scattered over the pleural surfaces of the lungs, which presented on section small areas of consolidation.

The heart weighed 370 Gm. The valves on the right side of the heart were thin and delicate. The mitral valve adjacent to the anterior papillary muscle was ulcerated. To it was attached a large friable, fungating vegetation. Directly in apposition there was a smaller vegetation. The ulceration beneath the larger vegetation extended for a short distance into the wall of the left auricle. The aortic cusps were regular and not fused. On the corpus arantii of the anterior valve leaflet there was a small, fresh friable vegetation. The myocardium appeared mottled with pale red and light brown areas. Minute circumscribed opaque areas were found in the wall of the left ventricle a few millimeters beneath the epicardium. A small infarct was observed in one kidney and several infarcts were present in the spleen.

The ovaries and tubes appeared normal. The uterus was small and firm; when it was opened a necrotizing endometritis was found. Microscopic examination revealed an organizing thrombosis of the parovarian veins.

The hemolytic streptococcus isolated repeatedly from blood and uterine cultures was identified as group B by the method of Lancefield. The micro-organism differed from group C in that the growth on rabbit blood agar was firmer in consistency and more opaque. Marked hemolysis was noted both aerobically and anaerobically on blood agar plates. A slide agglutination test with the patient's serum gave a 4 plus reaction.

On the basis of the clinical course of the patient the port of entry of the streptococcus was probably the uterus, although the necropsy showed little evidence for this pathogenesis of the bacterial endocarditis.

Bliss and her collaborators³ have shown that sulfanilamide in broth in a dilution of 1:10,000 has a definite bacteriostatic effect on strains belonging to groups A, B and C but not D or E. The best results were obtained with A, although good results were obtained with B and C. They also noted that sulfanilamide is of value in the treatment of infections in animals caused by streptococcus of group C. Seastone⁴

noted the favorable effect of sulfanilamide therapy on guinea pigs infected with two strains of group C. Colebrook and Purdie,⁵ however, observed that with one group C strain they could obtain only a slight protective effect in mice.

Since in both of the cases here reported sulfanilamide therapy was disappointing, experiments were undertaken to determine the effect of the drug on these particular strains of streptococci. Streptococcus cultures were grown in infusion broth for eight hours at 34 C. Serial dilutions in broth of 10^{-5} , 10^{-6} and 10^{-7} were made from these cultures and sulfanilamide was added until final concentrations of 1:10,000 were obtained. Similar tubes without sulfanilamide were prepared as controls. The two series of cultures were examined for presence and amount of growth after incubation at 37, 34 and 22 C. for fifteen hours. No difference could be detected in the rate of growth in the sulfanilamide tubes as compared with the controls, so that it was believed that little if any bacteriostasis occurred. Recently, however, White and Parker⁶ have found that bactericidal action due to sulfanilamide cannot be demonstrated at a test temperature lower than 39 C. Evidence has been reported by Levaditi and Vaisman⁷ that sulfanilamide exerts its effect on the streptococcus through its influence on the capsule of the micro-organisms. Experiments carried out in the Hoagland Laboratory of the Long Island College of Medicine⁸ show that temperatures between 39 and 41 C. exert a profound influence on the development of the streptococcus capsule, and it is possible that a bacteriostatic effect might have been demonstrated if incubation had been carried out at higher temperatures than 37 C.

To test experimentally the chemotherapeutic effect of sulfanilamide on these strains of streptococci of groups B and C, white mice weighing from 18 to 20 Gm. were inoculated with cultures of the micro-organisms. Infusion broth cultures grown for fifteen hours at 37 C. were diluted from 10^{-1} to 10^{-7} . For each of the serial dilutions six mice were inoculated, each being given intraperitoneally 0.5 cc. of the culture dilution. Immediately after the peritoneal injections three mice in each series were given subcutaneously 8 mg. of sulfanilamide. This dose was given daily for three days and 1 mg. daily for the six following days. The remaining mice served as controls. The control mice of group B which received dilutions of 10^{-1} to 10^{-5} died within one to eight days, those receiving the dilutions of 10^{-6} died within fifteen to eighteen days, and those given the dilution 10^{-7} survived for thirty days. The mice which were given sulfanilamide and which received culture dilutions of from 10^{-1} to 10^{-5} died within one to nine days, while those receiving dilutions of 10^{-6} and 10^{-7} survived for thirty days. Since the mice to which sulfanilamide had been administered died almost as early as the control mice, with the exception of the series of the 10^{-6} dilution, in which the treated mice survived and the controls died after fifteen days, one would be led to believe that sulfanilamide exerted only a mild chemotherapeutic effect on experimental infections in mice with this strain of group B streptococcus.

In the case of the group C streptococcus the control mice receiving dilutions of from 10^{-1} to 10^{-5} survived from one to six days, while the treated mice died between one and seven days after inoculation. Mice given dilutions of 10^{-6} and 10^{-7} of broth in the control and treated series survived for more than thirty days. There was thus no significant difference between the mice receiving sulfanilamide and the untreated controls.

We observed, however, as did Long and Bliss,⁹ that more phagocytosis occurred in the peritoneal exudate of the treated mice than in the controls. The infecting organism was recovered in a number of instances from the peritoneum and heart's blood of the control mice and from those which had received sulfanilamide.

COMMENT

The majority of human streptococcal infections are thought to be due to members of group A. Following Lancefield,² streptococci of group C have been regarded as pathogenic for animals rather than man. Among a number of strains of hemolytic streptococci from parturient women, Lancefield and Hare¹⁰ found several of group C, but only one was from a patient with a febrile puerperium. Bliss and her associates³ likewise have emphasized the lack of pathogenicity of group C for man. Evidence has been presented by others, however, that group C may be pathogenic for human beings. Hare,¹¹ Plummer¹² and Evans and Verder¹³ have noted that it may cause erysipelas. Plummer found among forty-seven cases of puerperal infection due to streptococci forty-four of group A and two of group C.

Congdon¹⁴ classified the streptococci from twelve cases of septic abortion. Eight were of group A, two of group B, one of group C and one of group D. The two fatal cases, however, belonged to group A. Evans and Verder found fourteen strains of group C streptococci among thirty-six strains isolated from cases of puerperal infection. All occurred, however, during 1931 and 1932 when a wave of group C puerperal infection occurred in London similar to the wave of erysipelas infection due to group C which was observed in Baltimore in 1935. Colebrook and Purdie have reported two cases of puerperal infection due to group C in a series of 100 cases. In both, however, the infection was limited to the uterus, vagina and perineum. Fatal puerperal infection caused by group C is reported here for the first time to our knowledge.

Fatalities due to group B infections have been noted by several authors. Two cases reported by Fry¹⁵ showed vegetative endocarditis similar to that described here and caused by group B, but neither presented post-mortem evidence of uterine infection. In our group B case it was not conclusively demonstrated that the infection had entered through the uterus, but this seems probable. However, the picture presented by these three

cases of vegetative endocarditis, with little local reaction to indicate the port of entry, may prove to be characteristic of infections by the streptococcus of group B.

SUMMARY AND CONCLUSIONS

1. Two cases of vegetative endocarditis due to the hemolytic streptococcus groups B and C were observed. One was postabortal and the other probably post partum.

2. Death due to infection in the human being by the hemolytic streptococcus group C is reported for the first time to our knowledge.

3. Massive sulfanilamide therapy failed in both cases. The retention of infected placental tissue may have been a contributory factor in one case.

4. In vitro and in vivo experiments to determine the effect of sulfanilamide on the particular strains of streptococci found in these two cases were carried out. The results indicated little or no chemotherapeutic effect.

NEUROTIC SYMPTOMS AND CHANGES OF BLOOD PRESSURE AND PULSE

FOLLOWING THE INJECTION OF EPINEPHRINE

S. H. KRAINES, M.D.

AND

IRENE C. SHERMAN, M.D.

CHICAGO

Our purpose in this study was (1) to observe the effect of epinephrine on the blood pressure and pulse rate of psychoneurotic and normal persons and (2) to compare the sensations following the injection, as given in subjective reports, with the symptoms recorded in the patients' clinical records.

Goetsch,¹ in his study of the effect of epinephrine on patients with hyperthyroidism, found that these patients reacted actively to 0.5 mg. of epinephrine given subcutaneously, whereas normal persons showed no reaction to this dose. He further indicated that many conditions such as "queer nervous disturbances, psychasthenia, psychoneuroses, hysteria, neurasthenia, melancholia and arteriosclerosis" gave essentially negative results, although in a few of these cases some acceleration of pulse and a slight rise of blood pressure occurred, but no subjective symptoms; or a slight transient reaction was observed.

Goetsch described a positive reaction to epinephrine as an early rise of blood pressure and pulse rate of over 10 points at least. He observed that many times there was a considerable increase in pulse rate, without much increase in blood pressure but with an increase of "signs and symptoms."

Tompkins and her associates,² in reporting a study in which Goetsch's procedure was utilized, further elaborated the typical epinephrine response, stating that diastolic pressure may rise, fall or remain unaltered. Parallel with these changes they noted an increase in

given characteristic signs and symptoms such as tremor, vasomotor reactions, palpitation and precordial pain. None of the normal persons they tested showed any of these reactions.

Our study was carried out on twenty-five psychoneurotic patients, fourteen men and eleven women, and on nineteen nurses and students, fourteen men and five women. The patients were all registered in the dispensary and came by appointment for the special observations.

Each subject was told to lie down on the examining table and relax and was informed that he was to be given an injection but was not told of what it consisted. The blood pressure and pulse rate were then recorded at frequent intervals, about one minute apart, until it was determined that a stable systolic blood pressure level had been reached.

The time interval before a fairly stable level was attained varied from subject to subject, the range being from three to twenty-seven minutes (average ten minutes) for patients and from three to eighteen minutes (average six minutes) for the normal subjects.

It was noted that numerous conditions caused rather wide fluctuations in blood pressure and pulse rate in some instances during the preliminary observation period. One patient's systolic pressure, for example, rose 26 points and the diastolic pressure 20 points when one of the investigators entered the room; another increase of 28 points in systolic pressure and 10 points in diastolic pressure occurred during an interval of five minutes when the patient cried and spoke of being ashamed to complain when she was not really sick. Again, when a syringe was brought into the room another patient's systolic pressure suddenly rose 16 points and the diastolic pressure dropped 10 points.

These unusual variations were seen about as frequently in the normal group as among the psychoneurotic patients. In one instance the systolic pressure rose 20 points and the diastolic pressure 12 points at a moment when the subject was laughing. In another instance the pulse rate rose 20 points, and in two subjects the diastolic pressure dropped 20 points without apparent cause. For the most part, however, fluctuations of blood pressure and pulse rate were small during the preliminary observation period, the patients averaging 3.4 points for systolic pressure, 4.1 for diastolic pressure and 0.5 for pulse rate. The corresponding values for the normal subjects were -0.9 , $+0.8$ and $+0.6$.

When it was established that the blood pressure and pulse readings were fairly constant, 0.5 cc. of physiologic solution of sodium chloride was injected into the cubital vein for the purpose of control observations. Readings of blood pressure and pulse rate were taken as soon as the injection was completed and every half minute thereafter until it was apparent that these were stable. This time interval was in all cases less than ten minutes. The identical procedure was then repeated, except that the material injected was 0.01 mg. of epinephrine (0.5 cc. of a 1:50,000 solution in 0.9 per cent sodium chloride). Readings were again taken every half minute until a return to the initial level occurred, the maximum time interval being eight and one-half minutes for the normal subjects and ten minutes for patients.

After the observations following each injection had been completed, the subjects were asked to give a report of the feelings and sensations they experienced after the injection.

Table 1 shows the blood pressure and pulse changes which followed the injection of epinephrine. The maximum change in systolic pressure of patients was considerably larger than of the normal subjects, 68 versus 40 mm. of mercury, and the range was almost twice as great. The average change was 24.3 mm. for patients and 18.5 mm. for the normal group, a difference of 5.8 mm. The coefficient of reliability of this

* Pulse records were not obtained in all cases.

† Coefficient of reliability = $\frac{\text{Difference}}{\text{Probable error of difference}}$. This value should equal 3 to be statistically reliable.

difference, however, was not sufficiently large to indicate that the difference was statistically reliable. Likewise, the differences in diastolic blood pressure and pulse rate were not significant. A striking fact noted in connection with diastolic pressure was its tendency either to rise or to fall after the injection of epinephrine. Pulse rate, too, tended to decrease in some instances, but on the whole upward changes predominated.

TABLE 2.—Changes in Blood Pressure and Pulse Following the Intravenous Injection of 0.5 Cc. of Physiologic Solution of Sodium Chloride

		No. of Cases*	Change		Standard Deviation	Probable Error		C. R.
			Mini-Mum	Maxi-Mum		Mean	Difference

	Controls	15	0	14	1.9	7.8	1.255	
Pulse	Patients	16	0	20	2.4	8.5	1.433	1.913
	Controls	17	0	16	1.7	7.5	1.239	

* The number of cases does not correspond to that in table 1 because not all subjects received salt solution.

Table 2 shows the changes in blood pressure and pulse rate following the injection of physiologic solution of sodium chloride. All three types of measure tended either to decrease or to increase, although the maximum increases in all instances were greater than the maximum decreases. Differences between the patients and the normal group were negligible and not statistically reliable.

Table 3 shows a comparison of blood pressure and pulse reactions to epinephrine and salt solution. The average change in blood pressure and pulse rate of both the normal and the psychoneurotic groups was strikingly lower after the injection of salt solution than of epinephrine, except for diastolic pressure. The average change in diastolic pressure was greater after salt solution owing to the fact that there were a great many more and larger decreases (negative values) in diastolic pressure after epinephrine, which tended to lower (make less positive) the average change. The coefficients of reliability were so small, however, that the differences in diastolic pressure following the injection of epinephrine and of salt solution cannot be regarded as significant.

In a review of the literature based on studies of subcutaneous injections of epinephrine, Grill³ stated the variations in the epinephrine effect depend on the initial blood pressure and that when this is low one has to reckon with a relatively poor effect. He maintained

that the best effect is obtained at the normal blood pressure level and that with increased pressures the effect again is poor. Our study does not confirm this idea.

According to table 4, the maximum rise of systolic blood pressure of psychoneurotic patients following the injection of epinephrine was least when the initial pressure was low and increased directly with an increase in the initial level. The opposite was true in the normal group, the rise of systolic pressure tending to be less as the initial pressure increased. This suggests that some psychoneurotic individuals may be sensitized to epinephrine, owing to its overproduction in the body under emotional conditions.

Table 5 shows the variety of symptoms expressed by the subjects after the administration of epinephrine. Palpitation, weakness and trembling were most commonly described by the patients and sensations of

3. Grill, C.: Observations on the Adrenalin Need in Man and the Effect on the Blood Pressure at Different Blood Pressure Levels. *Acta med. Scandinav.* 91: 628-647, 1937.

warmth by the normal group. The latter also frequently mentioned palpitation, weakness, trembling and breathing difficulties.

In only two instances were similar reactions described after the injection of salt solution. One patient stated that he felt his heart "pumping" and that he was a little excited but not afraid. Another commented on the fast beating of her heart. All other subjects stated that they felt no difference following the injection of salt solution.

It was striking that in thirteen of the twenty-five patients, or more than half, the symptoms following the administration of epinephrine corresponded at least in part to the presenting complaints. Remarks such as the following were made by these patients:

I feel just like this when I get a spell at home.
That's just the way I always feel.
I had this funny feeling in my stomach before.
I have these numb spells anyway.
I feel attacks like this when I go to bed at night.
When I make myself work I feel this way.
I have pain in the right leg like I usually have.
I feel taut on the right side, the same sort of thing as usual, but worse.

My heart flutters like when I feel weak. At those times my heart feels sort of fluttery.

My feelings were on the same order as my first attack.

I have these funny sensations often when I feel weak in the legs and shaky all over.

Perspiring is an ordinary symptom of mine.

I feel weak and trembly, like crying. Ordinarily when I get tired my hands are shaky and I cry.

The close correspondence between the sensations the patients described after injection of epinephrine and their usual psychoneurotic symptoms may be further evidence that the complaints of some psychoneurotic patients are due to the overproduction of epinephrine.

COMMENT

Many "neurotic" symptoms are obviously not purely imagined. The increase in heart rate, perspiration of the palms and spasm of the intestinal musculature are all physiologic reactions, although their etiology may be psychologic. From our observations it appears that epinephrine may be one of the mediating agents of these reactions. Our subjects had no fear of the injection, as evidenced by the small reactions to physiologic solution of sodium chloride and by the lack of subjective complaints following the injection of salt solution. Epinephrine was given "simply as a repetition" of the first injection, and yet the signs and symptoms following it were quite definite.

A coterie of signs and symptoms was common to most subjects, normal or psychoneurotic. These included deep sighs, pallor, palpitation, weakness and trembling. It was interesting to note that the frequency of symptoms produced by epinephrine was roughly the same in normal subjects and psychoneurotic patients, which may be further evidence that most of the symptoms described were not psychic and imagined but were produced by epinephrine.

Another observation was that existing "psychoneurotic" symptoms were markedly aggravated by epinephrine. Many patients a few moments after the injection of epinephrine spoke of "feeling just like this" during a "nervous" attack. The complaints of some patients were general, consisting mainly of weakness and trembling. Others described sensations localized in the stomach, heart, legs and other parts of the body. One patient who complained of "sciatic pain"

which was not present after the injection of salt solution felt the pain acutely for several minutes after epinephrine was injected. This suggests that there may be a locus which when stimulated gives rise to local symptoms. The question arises whether pain and other symptoms of organic origin may not be aggravated by epinephrine. This possibility is now being investigated.

Normally the secretion of epinephrine is sufficient to maintain blood pressure, normal glycogenolysis and other functions, the amount secreted varying with the person and the situation. Because of the relation of the adrenal glands to the autonomic nervous system, the amount of flow presumably is proportionate in some degree to the activity of this part of the nervous system. States of excitement and fear may produce stimulation of the autonomic system, and as the psychoneuroses are associated with obvious or repressed emotional conflict they are likely to produce such stimulation.

No doubt the patient feels his symptoms keenly, and he refuses to believe they are imaginary. He can

be persuaded, however, to realize that while his symptoms are real and due to autonomic stimulation they are a part of his emotional reaction.

SUMMARY

1. The systolic blood pressure and pulse reactions of both psychoneurotic and normal persons are significantly greater following the intravenous injection of epinephrine than of salt solution. A similar difference in diastolic blood pressure was not observed.

2. The differences in blood pressure and pulse reactions between normal and psychoneurotic persons following intravenous injection of epinephrine are not statistically reliable.

3. The diastolic blood pressure tends to fall as often as it rises after the intravenous injection of epinephrine.

4. Epinephrine administered intravenously in dosage sufficient to produce changes in blood pressure and pulse rate produces similar signs and symptoms in normal and in psychoneurotic persons. These symptoms are similar to those commonly described by psychoneurotic patients.

5. Epinephrine aggravates existing psychoneurotic symptoms and may activate given latent symptoms.

6. From the therapeutic point of view, a patient will accept the fact that his symptoms are organic and not imaginary, although their basis may be psychologic.

30 North Michigan Avenue.

PROGNOSIS IN SCHIZOPHRENIA

RAYMOND L. OSBORNE, M.D.

HARTFORD, CONN.

Schizophrenia is a major medical and economic problem. Twenty-one years ago Pollock said:

If some unknown disease should strike down and kill 1,000 young people in New York City during the current year, do you think the medical profession, the newspapers, and the public generally would view the matter with complacency? Yet dementia praecox will come into this city as a masked enemy and steal away the minds of 1,000 young men and women and condemn them to a living death this year . . . and scarcely no public mention of the matter will be made.

A true rebirth phenomenon has insidiously manifested itself during the past half decade. It has been given impetus by the report of Meduna on the convulsive treatment of schizophrenia through the use of pentamethylenetetrazol (metrazol, cardiazol). The results achieved by Sakel using insulin as a method of inducing pharmacologic shock received wide publicity.

The great attention focused by these forceful attacks on a recalcitrant syndrome has been of inestimable value in an unforeseen direction, for regardless of the validity

TABLE 1.—First Admissions (339)

and worth of the pharmacologic shock as therapy that technic has attracted long needed allies to the side of psychiatry in its struggles to elucidate the nature of schizophrenia. The biochemist, the physiologist and the pharmacologist, long protesting against the esoteric and impalpable material of psychology, allowed themselves a taste and now want a bite.

Psychiatry is not fixed. Its tenets shift gradually, and its criteria change with time. Standards used two decades ago are now discarded. To measure anything one must have a standard of comparison. The worth of the pharmacologic shock treatment in schizophrenia can be adjudged only with a greatly increased number of cases, accompanied by adequate controls, observed over a long period of time.

With this goal in mind I undertook to study all the cases of schizophrenia admitted during one fiscal year to the Rockland State Hospital for two reasons: first, because of the need for controls for comparative purposes in the pharmacologic shock group and, secondly, because I wished to evaluate the work done at this hospital. The hospital receives patients committed from New York City (boroughs of Manhattan, Bronx and Richmond) and the county of Rockland.

The year 1935 was picked for these reasons: (1) There was a change in the New York State Department of Mental Hygiene Statistical Guide, with the introduction of a new classification approved by the American Psychiatric Association in 1934, which par-

tially invalidated the old New York State statistics for the comparative purposes necessary; (2) this year antedates the introduction of the shock treatment at Rockland; (3) it offers a good statistical sampling, for there are more than 500 cases, and (4) all the diagnoses at Rockland during that year were made by one man.

RESULTS

In a total of 536 cases admitted during the year there were twenty deaths due to extraneous causes and twenty-five transfers into and out of the hospital. Of

the remaining 491, 339 were first admissions and 152 were readmissions; the latter had been admitted to hospitals other than Rockland or had previously been admitted to this hospital. The patients are grouped by type and sex as follows: simple type, twenty-three males and eight females; hebephrenic type, seventy-one males and sixty-seven females; catatonic type, fifty-three males and sixty-six females; and paranoid type, 144 males and 103 females. In addition, there was one female with a mixed type of the disease.

Thus there is a slight preponderance of males over females except in the catatonic type. In all there were 291 males against 245 females. The most frequent type encountered is the paranoid, followed in order by the hebephrenic, catatonic and simple types.

The syndrome strikes youth. The average age on admission for thirty-one patients with simple schizophrenia, was 26.8 years; for 138 with the hebephrenic, 25.6 years; for 119 with the catatonic type, 25.9, and for 247 with the paranoid, 33.5 years. Thus the oldest group is the paranoid and the youngest the hebephrenic.

The length of time the patients were noticeably psychopathic is of interest. It is found that those with the paranoid type are able to adjust themselves in the outside world the longest. The patient with the catatonic type is hospitalized soonest after onset, followed by the hebephrenic and simple types. The duration of illness in days before hospitalization for first admission alone is 694 for the simple type and 593 for the hebephrenic, 519 for the catatonic and 712 for the paranoid type. Readmission for the catatonic type occurs very soon after exacerbation of the illness.

A study of the average length of hospital stay from admission to parole in cases in which remission occurs

From the Rockland State Hospital, Orangeburg, N. Y.
Read in part before the Interhospital Conference of the New York State Hospitals at the Psychiatric Institute and Hospital, New York, April 8, 1938.

shows that the longest hospitalization results from catatonia and the shortest from simple schizophrenia. The average hospitalization in days of paroled patients is simple type 212, hebephrenic type 270, catatonic type 329 and paranoid type 225.

The tables show the number and percentage distribution of the paroled and discharged patients in the various types for first admissions alone, readmissions alone and for the two groups together. One is struck in table 1 by the very high parole rate among first admissions, for an average for all types and for both sexes of 44 per cent is paroled. Noteworthy is the astonishing percentage of paroles and discharges in the catatonic groups, with 65 per cent and 55 per cent of females and males respectively improving sufficiently to go home, and this without special treatment. The simple type also shows a high rate, but the number of cases is less. The hebephrenic rate fits in with the conception of the more serious and refractory nature of this reaction type, for this group has the lowest parole rate, while the paranoid type is next. Table 2 shows that the parole rate for readmitted cases of the catatonic type has dropped and is next to the lowest, closely approximating the hebephrenic type, which maintains its negative leadership. The simple type remains highest and the paranoid type is in about the same position as for first admissions. Table 3 combines the preceding two tables: the simple and catatonic types offer the best prognosis, closely followed by the paranoid type, the hebephrenic type being left far behind, in accordance with preexisting concepts.

The question of how many persons have previously been patients and have been paroled or discharged before may be brought up. It is found that of both sexes 28 per cent of all those discharged and paroled had previously been admitted for this condition; the remainder had been hospitalized for the first time.

SUMMARY

1. The most frequent reaction type encountered in this study is the paranoid, followed in order by the hebephrenic, catatonic and simple types.
2. The oldest group is the paranoid, the youngest the hebephrenic type.
3. The catatonic type is hospitalized most quickly after onset; then follow the hebephrenic and simple types; the patients of the paranoid type are able to adjust the longest with their psychoses.
4. In cases of readmission, the longest hospital stay results from catatonia, the shortest from simple schizophrenia.
5. Among first admission only, 67 per cent of the simple type, 59 per cent of the catatonic, 41 per cent of the paranoid and 32 per cent of the hebephrenic type are paroled. This is an average of 44 per cent for all types.
6. Among readmissions only, 67 per cent of the simple type, 43 per cent of the paranoid, 30 per cent of the catatonic and 28 per cent of the hebephrenic type are paroled, an average of 37 per cent.
7. The prognosis for second attacks is poorer.
8. The prognosis in simple schizophrenia is best; the catatonic type has a relatively good outlook for the first attack and a poor one for subsequent episodes, approaching the uniformly poor prognosis held out for the hebephrenic type. Patients with paranoid schizophrenia have a fair outlook, unchanged by previous hospitalization. These patients do not deteriorate so rapidly as the catatonic and hebephrenic types, and so their parole rate is constant.

9. The best ultimate prognosis is held by the simple and catatonic types, followed by the paranoid and lastly by the hebephrenic type.

10. Of all those paroled or discharged, 72 per cent had only one admission and 28 per cent were paroled more than once.

CONCLUSIONS

The prognosis in schizophrenia is not so hopeless as is generally believed. Among patients on their first admission in this study, 44 per cent remitted spontaneously and were able to return to their homes.

Although the results reported with pharmacologic shock treatment are, so far, decidedly favorable, especially as far as it seems to cut down the length of hospital stay before remission in early cases, psychologic implications must not be overlooked. A deep regression occurs during stupor or convulsion out of which a new environmental adaptation follows. The intensified relation of patient to physician and added nursing care may be the factors which promote rapid remission.

It must not be forgotten, as the previous figures show, that spontaneous remission is as frequent or almost as frequent as pharmacologically induced remission.

171 Washington Street.

GASTRIC PERISTALSIS AFTER PYLO- ROTOMY IN INFANTS

WITH SPECIAL REFERENCE TO POSTOPERATIVE
CARE OF PYLORIC STENOSIS

HAROLD K. FABER, M.D.

AND

JOSEPH H. DAVIS, M.D.

SAN FRANCISCO

For nearly a quarter of a century it has been customary in postoperative management of infants who have undergone the Fredet-Rammstedt operation of pylorotomy for hypertrophic pyloric stenosis to begin the administration of water and milk very soon after operation and to repeat it at frequent intervals. Morgan,¹ the first to outline the treatment in detail, advised giving 16 cc. of water one hour after operation, following it with 16 cc. of slightly diluted breast milk an hour later and thereafter alternating water and milk in gradually increasing amounts about every one and one-half hours. Strachauer² begins feeding from three to four hours after operation. Paterson³ begins at four hours, giving 4 cc. hourly and gradually increasing the amount. Page⁴ begins an hour or two after operation. Lanman and Mahoney⁵ begin at two hours with water and repeat at two hour intervals, later using whey and breast milk. Norris,⁶ however, gives nothing by mouth for six hours but then gives 15 cc. of breast milk every thirty minutes for four hours. Cobb⁷ gives water immediately after recovery. Thompson and Gaisford⁸

give 8 cc. of water two hours after operation and alternate formula and water thereafter at two hour intervals. Donovan⁹ starts water at two hours, gives 8 cc. of milk at four hours and follows with milk at three hour intervals thereafter. Harris,¹⁰ like Norris, gives nothing by mouth for the first six hours and then gives 4 cc. of breast milk every hour. Rowe¹¹ starts water two hours after operation and repeats it every fifteen minutes; he starts milk at eight hours and repeats it at three hour intervals. Holt and Howland¹² advise starting with from 5 to 10 cc. of breast milk as soon as the infant recovers from the anesthetic, repeating it every three hours and giving water between feedings.

Griffith and Mitchell¹³ start water or sugar solution "a few hours" after operation and milk at six or eight hours. Parmelee¹⁴ starts with 8 cc. of Ringer's solution and dextrose as soon as the infant is awake and repeats every two hours; an hour after the first solution, 15 cc. of breast milk is given and also repeated every two hours; thus the infant receives solution or

laparotomy for other diseases and that the usual conservative rule of giving water very sparingly immediately after operation and no food for the first twenty-four hours must be disregarded. The conservative practice is based on a desire to minimize postoperative vomiting and on recognition of the fact that after operations on the abdominal organs normal peristalsis is often temporarily suspended, so that, even when not vomited, ingested material in the stomach will not be passed on into the intestine and absorbed. That post-operative vomiting after pylorotomy is frequent and often troublesome was noted by Morgan and other writers and has certainly been our own experience when following the usual schedule of early and frequent feedings. We were led by this observation to wonder whether the condition of temporary inhibition of peristalsis might not occur after pylorotomy as well as after other abdominal operations and, if so, whether the classic method of postoperative management of pylorotomy is altogether wise.

Postoperative Rates of Gastric Emptying *

7	5	11½	18 (90%)	26½ (50%)	..	29½	Small amount still in stomach at 29½ hours
8	2	8	18 (60%)	..	24 (30%)	48	No examination between 24 and 48 hours
9	2	3	4 (93%)	..	16 (40%)	22	
10	2	6½	9½	19 (80%)	..	24	

* The stated hours are dated from the time of operation. The percentages indicate the amount of retention as estimated by the roentgenologist.

milk every hour. Wyatt¹⁵ gives 15 cc. of water two hours after operation and 15 cc. of milk two hours later; the alternation is continued during the first day. The total amount of fluid plus milk (usually breast milk) for the first twenty-four hours has been estimated by us to range from 4 ounces (120 cc.) to 16 ounces (480 cc.) and the time of first administration from about half an hour to six hours after operation. The intervals between feedings of water or breast milk range from fifteen minutes to two hours. These intervals, it should be noted, are much shorter than those ordinarily used in the feeding of babies.

It is evident that practically all writers on the subject believe that much earlier oral administration of fluid and food is required after pylorotomy than after

For these reasons we have determined the rate and extent of gastric emptying during the period immediately following operation in ten cases. The operation in all instances was the standard Fredet-Rammstedt. From one to five hours after the infant returned from the operating room a teaspoonful of barium sulfate, suspended in an ounce of water, was given by mouth. Periodic examination at convenient intervals were made by fluoroscopy and roentgenograms for from twenty-four to forty-eight hours until the stomach was empty or practically so. Nothing else was given by mouth in most of the cases until that point had been reached, the fluid needs being met by hypodermoclysis. The accompanying table gives the results of the inquiry.

Omitting case 2, in which barium sulfate was not fed after operation, it will be observed that complete retention lasted from three to eleven and one-half hours (average, nine cases, 8.9 hours), that emptying was first noted from five to eighteen hours after operation (average, seven cases, 11.2 hours), and that emptying was not complete until from twenty to twenty-nine and one-half hours after operation (average, nine cases, counting the emptying time in cases 1 and 8 as twenty-five hours, 24.5 hours). Attention is called especially to cases 1, 5 and 8, in which from 30 to 50 per cent of the ingested barium sulfate remained in the stomach twenty-four hours after operation.

GASTRIC PERISTALSIS—FABER AND DAVIS

Protocols of the individual cases are given at the end of the paper.

COMMENT

It is clear that after pylorotomy for infantile pyloric stenosis gastric peristalsis is completely inhibited for several hours and is much depressed for twenty-four hours or more. Case 5 is of special interest in showing how long it may require to return to normal. This is the only case in which we had subsequent barium sulfate tests after the first day; these showed that on the third postoperative day emptying was still slow while on the twentieth day it was quite normal.

The peristaltic depression after operation is, we believe, closely related to postoperative vomiting and distention and, having demonstrated it, we believe that the schedule of early postoperative feeding now in general use should be revised. It may well cause or increase of breast milk or formula every four hours, and on successive days we rapidly increase the amount up to the normal for size and need. With formula-fed babies we often employ thick cereal feedings at first, diluting them after a day or two or changing to ordinary fluid formulas. Under this plan of management vomiting, although not entirely eliminated, has been considerably lessened, and no serious postoperative difficulties have been encountered.

For these reasons we have adopted the policy of withholding both water and food for about twenty-four hours after operation and of administering fluid parenterally during that time and usually also on the next day. On the second day we offer an ounce (30 cc.) of breast milk or formula every four hours, and on successive days we rapidly increase the amount up to the normal for size and need. With formula-fed babies we often employ thick cereal feedings at first, diluting them after a day or two or changing to ordinary fluid formulas. Under this plan of management vomiting, although not entirely eliminated, has been considerably lessened, and no serious postoperative difficulties have been encountered.

It may be pointed out that today infants with pyloric stenosis rarely come to the pediatrician and surgeon in the state of extreme malnutrition and dehydration which was so common a few years ago and which made the administration of food and fluid by mouth at the earliest possible moment seem exceptionally urgent. This was probably the basis for what now seems to us an undue haste in postoperative feeding. It appears not unreasonable that in the future the same general policy of postoperative feeding should be used after pylorotomy for pyloric stenosis as after laparotomy for other diseases.

CONCLUSIONS

1. After pylorotomy for hypertrophic pyloric stenosis there is a profound and prolonged depression of gastric peristalsis, which regularly lasts for about twenty-four hours and may last three or more days. In the average case evacuation of material ingested soon after operation does not begin for over eight hours and is not complete until twenty-four hours after operation. In our opinion this depression of peristalsis is closely related to postoperative vomiting, which is common and often persistent for several days after the Fredet-Ramstedt operation.
2. For these reasons the traditional early and frequent administration of water and food during the first postoperative day does not seem either logical or desirable, nor is the reason apparent why it should be considered urgent. It is suggested that the same general plan of postoperative management should be applied to pylorotomy as to other abdominal operations, food being withheld for about a day and water given very sparingly at first.

PROTOCOLS

The preoperative symptoms and signs were typical in all cases, and the diagnosis of hypertrophic pyloric stenosis was confirmed at operation.

CASE 1.—A boy aged 4 weeks was given barium sulfate mixture two hours after operation. Examinations three, five and seven hours after operation showed that no barium sulfate had left the stomach. At ten hours not over 10 per cent was out. At twenty-two hours the stomach was almost half empty. At twenty-four hours there was still 50 per cent retention; this was the last examination. Administration of water by mouth was begun at twenty-six hours and of formula at thirty-three hours. There was no postoperative vomiting.

CASE 2.—A boy aged 3 months had been given barium sulfate a few hours before operation, and no additional barium sulfate was given afterward. Examinations at frequent intervals after operation showed no peristaltic activity of the stomach for twenty-two hours. At twenty-four hours he was given 1 ounce (30 cc.) of thick formula. At twenty-five hours most of the barium sulfate had left the stomach and a peristaltic wave was seen for the first time.

CASE 3.—A girl 1 month old was given barium sulfate two hours after operation. Three hours after operation no peristalsis and no emptying were seen. At five hours a few drops had left the stomach. At seven hours the stomach was one-third empty; at thirteen hours the stomach was almost empty, and at twenty-three and a half hours only a few drops remained in the stomach near the pylorus. None at all remained at twenty-six hours. Feeding of thick cereal formula was begun at twenty-four hours, and the food was retained.

CASE 4.—A boy aged 1 month was given barium sulfate five hours after operation. Emptying had not occurred six and a half and eight hours after operation. It was first seen at fourteen hours, and at twenty-four hours the stomach was two-thirds empty. At twenty-six and a half hours a trace was still present. At this time liquid formula was given but was vomited. Thick cereal formula was retained.

CASE 4.—A boy aged 1 month was given barium sulfate shortly after operation. None had passed out of the stomach at two, six and ten hours. At twenty hours only a drop remained. Thick cereal feeding was started twenty-six hours after operation, and the food was retained.

CASE 5.—A boy aged 3 weeks was given barium sulfate five hours after operation. No emptying had occurred six and a half and eight hours after operation. Evacuation had begun at fourteen hours, and the stomach was only two-thirds empty at twenty-four hours. At twenty-six and a half hours a trace remained in the stomach. Fluid formula given at this time was vomited. Thick cereal (1 ounce) was given and retained. A second barium sulfate test was made two days later. One fourth of the amount ingested had left the stomach at two hours and 50 per cent at four and a half hours, and the stomach was then emptying rapidly. Twenty days after operation a third test showed normal peristalsis; 50 per cent of the barium sulfate had emptied at one hour and none was left in the stomach at four hours.

CASE 6.—A boy aged 7 weeks was given barium sulfate four and a half hours after operation. There was no emptying half an hour later. At seventeen hours 40 per cent of the barium sulfate still remained in the stomach. At twenty-three hours emptying was complete. Formula given at twenty-three hours was retained.

CASE 7.—A boy aged 1 month was given barium sulfate five hours after operation; none had left the stomach half an hour or eleven and a half hours after operation. At eighteen hours there was still almost 90 per cent retention and at twenty-six and a half hours 50 per cent. At twenty-nine and a half hours a small amount of barium sulfate still remained in the stomach. Formula was started at twenty-six hours, and for the first few feedings small amounts were vomited.

CASE 8.—A boy aged 1 month was given barium sulfate two hours after operation. None had left the stomach eight hours after operation. At eighteen hours 60 per cent

in the stomach and at twenty-four hours 30 per cent. At forty-eight hours, the time of the next examination, the stomach was empty. Feeding was begun at forty-eight hours. Some vomiting occurred.

CASE 9.—A girl aged 3 weeks was given barium sulfate two hours after operation. Three hours after operation none had left the stomach and four hours after only 5 per cent. At sixteen hours 40 per cent remained in the stomach. At twenty-two hours emptying was complete. Fluid formula given at twenty-four hours was vomited, but thick cereal was retained.

CASE 10.—A boy aged 6 weeks was given barium sulfate two hours after operation. Emptying had not occurred three and a half and six and a half hours after operation and was first noted at nine and a half hours. At nineteen hours 80 per cent was still in the stomach. At twenty-four hours the stomach was empty.

Stanford University Hospital.

STUDIES ON PRESERVED HUMAN BLOOD

I. VARIOUS FACTORS INFLUENCING HEMOLYSIS

ELMER L. DeGOWIN, M.D.

JOHN E. HARRIS, Ph.D.

AND

E. D. PLASS, M.D.

IOWA CITY

The current interest in the use of preserved human blood for transfusions has been especially motivated by economic pressure in the United States and by military necessity in Europe. Hence the empirical clinical use of transfusions of preserved blood has tended to precede rather than to follow fundamental objective biologic and chemical studies in the laboratory.

A review of the literature reveals few data from which the clinician can establish satisfactory criteria for the use or rejection of preserved blood. Two factors appear to have contributed to this paucity of laboratory observations: first, the practice of blood transfusion has been so extensive and the indications have been so diverse that it is often difficult for the clinician to define precisely which elements of the transfused blood he most desires his patient to receive; second, the exact mechanism of the production of the various reactions from blood transfusions is not well understood. Consequently evaluation of the relative merits of fresh and preserved blood has been inordinately delayed.

There is considerable evidence that the intravenous injection of a large amount of hemolyzed blood may result in death, but the exact relation of hemoglobin to the production of severe transfusion reactions has not been determined. There is an apparent correlation between the occurrence of hemolysis in vivo and the incidence of severe renal damage, but whether the lesions of the kidneys are the result of the action of free hemoglobin itself or are caused by some other factor released by disintegration of the erythrocytes has not been conclusively determined. For a detailed statement of this aspect of the problem, the reader is referred elsewhere.¹ It is proposed until further studies are made

that preserved blood be considered unfit for transfusion if the hemoglobin content of the plasma is such that hemoglobinuria appears after the blood has been transfused.

In blood preserved by any technic the most obvious change occurs in the supernatant plasma, which sooner or later assumes the color of hemoglobin. It is not yet definitely established whether the erythrocyte must first rupture to give off its hemoglobin or whether it is possible for the pigment to diffuse out through small apertures in the cell membrane. Whatever the mechanism involved, the amount of free hemoglobin in the plasma of preserved blood may serve as a simple index of its suitability for use in transfusions and has consequently been used extensively for this purpose. Lichty, Havill and Whipple² have shown that there is a renal threshold for hemoglobin in the dog; more recently Ottenberg and Fox³ demonstrated a similar mechanism in human beings.

Rous and Turner⁴ in 1916 published the basic studies on the preservation of blood cells. They demonstrated that in general the rapidity of hemolysis is increased by the addition of electrolytes to the blood preservative mixture. On the contrary, when the serum was diluted with saccharose or dextrose the rate of hemolysis was much diminished. They devised a mixture consisting of three volumes of blood, two volumes of 3.8 per cent sodium citrate ($\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 + 5\frac{1}{2}\text{H}_2\text{O}$) in water and five volumes of 5.4 per cent dextrose which kept human red cells intact for four weeks. It was used to some extent in the British Medical Corps during the World War.⁵ In addition to the large volume this mixture had the disadvantage that the concentration of sodium citrate was too high for safe intravenous administration. Consequently the supernatant plasma was discarded and the cells were resuspended in saline or Locke's solution before being transfused.

In 1926 Perry⁶ reported extensive observations on the storage of blood with a dextrose-lithium citrate mixture which served as an excellent preservative. As with the Rous-Turner mixture, it was necessary to discard some of the plasma because of the high concentration of citrate. The use of lithium citrate merits further investigation. The workers at the Moscow Institute of Hematology later devised a mixture which has been widely used and which consists of sodium chloride 7.0 Gm., sodium citrate 5.0 Gm., potassium chloride 0.2 Gm. and magnesium sulfate 0.004 Gm. in 1,000 cc. of water. To this is added an equal volume of blood. Lindenbaum and Stroikova,⁷ at the Leningrad Research Institute for Blood Transfusion, compared this mixture with citrated blood and with the Rous-Turner mixture and concluded that the Moscow mixture inhibited hemolysis no better than did sodium citrate and not nearly as well as did the Rous-Turner mixture.

Gnoinski,⁸ of Warsaw, recently reported the successful preservation of blood in ampules from which the

air was excluded. He stated that the blood was "good" for ninety days. Scrutiny of the case histories of his six human recipients, however, reveals the fact that after transfusion two patients had fever and hemoglobinuria, three others had fever and only one had no transfusion reaction, and she received but 30 cc. of blood.

In reviewing all the experimental studies, one is impressed by the lack of quantitative data on hemolysis which makes exact comparison impossible. Although Rous and Turner pointed out that the presence or absence of hemolysis in sedimented blood could be determined only by examining the plasma after the cells had been resuspended and centrifuged out, many of the workers have not taken into account this slow diffusion of hemoglobin from the cell layer into the plasma. Practically all observers of hemolysis have used a grading system of 1 to 4 plus or no grading system at all. The only exception to this statement was found in the work of Scudder, Drew, Corcoran and Bull,⁹ and there the hemoglobin estimations were published incidentally to studies of plasma potassium. Statements are frequently made that blood can be preserved for a given length of time, although no acceptable quantitative data are presented to indicate the amount of actual hemolysis. Other than direct estimations of the amount of hemoglobin in the supernatant plasma are obviously valueless.

The object of the studies here reported was to determine the rates of hemolysis occurring in human blood in various preservatives and stored under a variety of conditions.

GENERAL METHODS

In the majority of the experiments the general procedure was the same. Erlenmeyer flasks of pyrex glass of from 1,000 to 1,500 cc. capacity were autoclaved with appropriate amounts of the preservative to be studied. When dextrose solutions were to be combined with other chemicals, the former were heated separately to avoid caramelization and later combined with the latter aseptically. Blood was drawn into the flasks from the median basilic veins of healthy men in quantities of from 400 to 600 cc. The blood was mixed with the preservative by gentle rotation of the receiving flasks. A 16 gage needle was used and connected to the flask by a 15 inch section of gum rubber tubing. Before the cells settled, the entire mixture was apportioned in 50 cc. quantities into 250 cc. Erlenmeyer flasks closed with cotton plugs. The entire lot was stored under identical conditions, and when an analysis was to be made the entire contents of one small flask were thoroughly shaken and the cells were centrifuged out. The supernatant plasma was then pipetted off and analyzed for hemoglobin. This procedure insured a uniform dilution of blood and preservative throughout the entire experiment and obviated the difficulties attendant on sampling the same flask repeatedly.

The refrigerator used was a room cooled by open coils of salt brine. The temperature was maintained at from 3 to 5 C. by an electrically controlled thermostat. Continuous records of the temperature were kept. The frost on the open refrigeration coils insured a high relative humidity and thus a minimum of evaporation.

Special precautions were taken to keep the blood away from sunlight or from prolonged exposure to artificial light.

In designing all preservatives an attempt was made to use isotonic solutions as determined by their depressions of freezing point. The freezing point of blood serum was taken as -0.56 C.

The following solutions were used in preservatives: 5.4 per cent anhydrous dextrose U. S. P. (Merek & Co., Inc.) in distilled water, 5.4 per cent anhydrous dextrose (Eastman Kodak Company) in distilled water, 3.2 per cent sodium citrate (Merek reagent grade, $\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 + 2\text{H}_2\text{O}$) in distilled water, 0.95 per cent sodium chloride U. S. P. in distilled water and heparin (Connaught Laboratories) in distilled water (sterilized by Berkefeld filtration).

Several methods of estimation of small amounts of hemoglobin were tried before final adoption of the method of Wu.¹⁰ This is a quantitative application of

Plasma hemoglobin values in blood mixtures stored in cotton-plugged flasks at 5 C. The values have been recalculated for differences in dilution when necessary to make them all comparable. The inset magnifies the details of the lower values by increasing the scale of the ordinates.

the benzidine test for hemoglobin in which a brown compound is compared in the colorimeter with a similar color developed in a standard hemoglobin solution. It was found possible to estimate accurately amounts as small as 1 mg. of hemoglobin in 100 cc. of plasma. No interfering substances were encountered in this test. Modifications of Wu's method were tried and found to possess no advantages over the original.

RATES OF HEMOLYSIS IN VARIOUS PRESERVATIVES

Preliminary experiments with the Rous-Turner mixture were sufficient to confirm the observations of those authors. The mixture used contained three volumes of blood, two volumes of 3.2 per cent sodium citrate (dily-

⁹ Scudder, John; Drew, C. R.; Corcoran, D. R., and Bull, D. C.: Studies in Blood Preservation, J. A. M. A. 112: 2263-2271 (June 3) 1939.

¹⁰ Wu, Hsien: Studies in Hemoglobin: III. An Ultra-Micro-Method for the Determination of Hemoglobin as a Peroxidase, J. Biochemistry 2: 189-194 (Jan.) 1923.

dric)¹¹ in water and five volumes of 5.4 per cent dextrose in water. This mixture contains a total concentration of sodium citrate of 0.64 per cent, which is considered too high to administer intravenously. Another disadvantage is that to give 500 cc. of blood a total mixture of 1,666 cc. would be required.

Modifications of this mixture were tried, and the one finally adopted contained ten volumes of blood, thirteen volumes of 5.4 per cent dextrose in water and two volumes of 3.2 per cent sodium citrate (dihydric) in water. This mixture has a total concentration of 0.25 per cent sodium citrate and provides a total volume of 1,250 cc. as a vehicle for 500 cc. of blood. The concentration of citrate is so low that the modified mixture, unlike the original Rous-Turner mixture, can be safely administered intravenously without discarding the plasma.

A series of experiments was performed with four different preservatives: ten volumes of blood, thirteen volumes of 5.4 per cent dextrose in water and two volumes of 3.2 per cent dihydric sodium citrate in water; thirty-three volumes of blood, four volumes of

of hemolysis were uniformly low during the first ten days, but between the tenth and the fifteenth day there was a sharp increase in the rate of hemolysis in the mixtures containing little or no added dextrose, while in the presence of a high concentration of the sugar hemolysis proceeded more slowly. At the end of from thirty to thirty-five days of storage there was from twenty-five to fifty times as much hemolysis in the mixtures poor in dextrose. This is graphically presented in the accompanying chart. It is hard to translate determined hemoglobin values into gross color changes but we have repeatedly noted that plasma in a test tube 20 mm. in diameter must contain at least 10 mg. of hemoglobin per hundred cubic centimeters before it is visible as a faint pink discoloration. Greater concentrations are difficult to estimate by direct inspection, even for those who have had practice comparing their gross visual judgments with quantitative estimations. Plasma containing 100 mg. of hemoglobin per hundred cubic centimeters is distinctly tinged with red but would probably be considered suitable for transfusion by the average worker.

* Blood was stored at 5 C. in flasks with cotton plugs.

† Observed values were multiplied by the dilution factor for comparison with values in other mixtures.

5.4 per cent dextrose in water and three volumes of 3.2 per cent dihydric sodium citrate in water; ten volumes of blood, thirteen volumes of 0.95 per cent sodium chloride in water and two volumes of 3.2 per cent dihydric sodium citrate in water, and twenty-three volumes of blood and two volumes of 3.2 per cent dihydric sodium citrate in water. In each instance the storage temperature was 5 C. and no attempt was made to exclude the air. The hemoglobin of the plasma¹² obtained by centrifuging specimens after thorough mixing was estimated at five day intervals of storage. Since the values obtained with this procedure depend on the number of erythrocytes subjected to hemolysis and the dilution of the plasma, recalculation was necessary in some mixtures to make hemoglobin values directly comparable with those obtained in mixtures containing ten volumes of blood and fifteen volumes of preservative. The results of these experiments are included in table 1. The values obtained show that there was progressive hemolysis in all preservatives during storage. The rates

THE EFFECTS OF TEMPERATURE ON HEMOLYSIS

It is generally stated that blood kept at room temperature will hemolyze more rapidly than in the refrigerator, and our experiences confirm this observation. Blood was drawn from one individual into the dextrose-citrate mixture previously described, apportioned into small flasks in 50 cc. samples and stored at room temperature (20 C.) in a dark cupboard. The flasks were placed in a shallow pan containing water and covered with a bell jar to increase the relative humidity and thus reduce evaporation through the cotton plugs. Plasma hemoglobin was determined after each two day period of storage. The values for plasma hemoglobin in milligrams per hundred cubic centimeters of plasma were as follows: no days, 2 mg.; two days, 69 mg.; four days, 95 mg.; six days, 86 mg.; eight days, 115 mg.; ten days, 94 mg.; twelve days, 458 mg. When these results are compared with those in experiment 12 (table 1), in which the blood was stored for the same period in the same preservative, but at 5 C., it will be seen that the same amount of hemolysis occurred in two days at 20 C. as in thirty days at 5 C.

11. The apparent deviation from the original concentration of sodium citrate is due to the fact that Rous and Turner used the salt with 5½ molecules of water of crystallization.

12. The term "plasma" is used in this paper to denote the noncellular portion of the blood plus the preservative solutions which dilute it.

A far more important temperature effect was discovered when we attempted to apply the facts obtained in the laboratory to the routine operation of a blood bank in the University Hospitals. In collecting blood to be preserved for transfusions it was the early practice to draw 500 cc. from each donor directly into an Erlenmeyer flask containing the preservative to be used. When 500 cc. of blood was drawn into from 50 to 100 cc. of sodium citrate solution no marked hemolysis was encountered, but when a similar amount was added to 750 cc. of the dextrose-citrate mixture (650 cc. of 5.4 per cent dextrose in water plus 100 cc. of 3.2 per cent dihydric sodium citrate in water) the blood in about one half of the flasks hemolyzed after only a few hours in the refrigerator. About 10 liters of blood was lost in this manner before the explanation became apparent. The temperature of the room where the blood was drawn was approximately 20 C. The temperature of the preservative had been brought to that of the room before the withdrawal of the blood. After following many false leads it was found that, if a 20 cc. sample was taken from the 1,250 cc. of blood mixture immediately after mixing and placed in the refrigerator beside

days of storage. Obviously, it is important to observe the precautions we have outlined if the dextrose-citrate mixture is to be used successfully.

THE RESISTANCE OF PRESERVED ERYTHROCYTES TO TRAUMA

Rous and Turner⁴ demonstrated that there is no direct relationship between the resistance of red blood cells to trauma (such as shaking) and their ability to remain intact in hypotonic solutions. The erythrocytes of some species are normally more fragile than others under such conditions, although they may resist trauma very well. It seemed desirable to investigate further the effect of trauma on the preserved human erythrocytes, since this question has a direct bearing on the transportation of blood for military purposes and is indirectly concerned with the disintegration of transfused erythrocytes in the circulation.

An arbitrary shaking test was devised based on the method of Rous and Turner. About 16 cc. of blood mixture was divided into two equal parts, the control portion of 8 cc. being kept at the same temperature as the portion to be tested while the remaining 8 cc.

* Arbitrary shaking test: 260 strokes per minute for thirty minutes.

the large flask, the blood in the small flask did not hemolyze while that in the large flask disintegrated within a few hours. Heating the preservative to body temperature before adding the blood did not prevent this initial hemolysis. Finally, the blood was drawn directly into the cold preservative which had just been taken from the refrigerator and the blood mixture was immediately returned to the cold room. This procedure effectively prevented initial hemolysis. This phenomenon has been encountered with citrated blood only when the room temperatures were extremely high (above 30 C.) and even then it has been prevented by drawing the blood into a flask placed in an ice bath. From the observations enumerated it seems logical to conclude that the almost immediate hemolysis observed in the earlier specimens was due to uneven cooling (from 37 to 5 C.) of various portions of a large volume of blood mixture which in some way destroyed many erythrocytes; when the blood was cooled rapidly and uniformly, this phenomenon did not occur. This would explain why hemolysis was rare in the presence of small quantities of citrate preservative but relatively frequent when larger volumes of blood mixture were employed without preliminary cooling. It should be emphasized that the phenomenon of hemolysis discussed in connection with the cooling of large quantities of blood occurs within a few minutes or a few hours after the blood is drawn and, so far as we can ascertain, has no relation to the slowly progressive hemolysis noted during many

was placed in a centrifuge tube of 15 cc. capacity, which was closed tightly with a rubber stopper. The tube was then clamped in a machine which shook the tube horizontally through its long axis at the rate of 260 complete strokes per minute for thirty minutes. At the end of the test both the shaken and the unshaken tubes were centrifuged simultaneously and the hemoglobin in the two samples of plasma was estimated.

between the plasma hemoglobin values in the two specimens was used to calculate the percentage of erythrocytes broken up by the shaking. This test was performed at five day intervals on stored blood from two donors in each of three preservatives. A summary of the results is given in table 2. While the values obtained and the method used leave much to be desired, the results show that there was a definite increase in fragility of red cells in all preservatives during the first ten days of storage. The erythrocytes stored in sodium chloride solutions were much more fragile than those stored in dextrose solutions. Whether this was due to some change in the cell membrane during storage in the saline solution or due to the protective action of the dextrose during shaking cannot be stated. Estimations of plasma viscosity and surface tension did not throw any light on the problem. The values obtained with citrated blood cannot be compared directly with those of the other two preservatives because each cubic centimeter contained 2.3 times as many erythrocytes, which in any standard shaking test

would increase the amount of trauma to which each cell was subjected. These observations would weigh heavily against the transportation of citrated blood for military purposes.

The data obtained from such violent shaking tests tend to show that the relatively slight trauma entailed in drawing the blood and mixing it with the preservative is probably not a significant factor in the development of hemolysis during storage.

THE EFFECT ON HEMOLYSIS OF THE EXCLUSION OF AIR DURING STORAGE

In the previous experiments blood mixtures were stored in flasks having the usual bacteriologic cotton plugs, which allowed free diffusion of atmospheric oxygen into the blood and of the blood carbon dioxide into the air. It seemed important to determine whether these changes had any appreciable effect on hemolysis during storage. Part of a blood preservative mixture was stored in the usual manner, while the other portion was poured into 50 cc. Erlenmeyer flasks, com-

rapidly than did blood exposed to the air or in an atmosphere of nitrogen.

Analyses of the content of oxygen, carbon dioxide and nitrogen conformed to the predictable values. The data will be published in another study.

PRACTICAL APPLICATIONS

Many of the facts demonstrated in the laboratory have been applied in the routine operation of the blood bank in the University Hospitals. The blood-dextrose-citrate mixture has proved practical and safe for human transfusions. Graduated Erlenmeyer flasks of 1,500 cc. capacity containing 650 cc. of 5.4 per cent anhydrous dextrose in water are autoclaved. Lots of 100 cc. of 3.2 per cent dihydric sodium citrate in water are autoclaved separately in flasks of 250 cc. capacity. These solutions are then stored in the refrigerator until required. Before the blood is collected, a two hole rubber stopper containing glass tubes is inserted in the mouth of the large flask, one tube being connected by rubber tubing to a glass adapter and a 16 gage needle

* Blood stored at 5 C. in flasks with cotton stoppers or with air excluded.

pletely filling them. Rubber stoppers were then inserted so that the remaining air and some blood were displaced through glass capillaries in the stoppers, and the capillaries were sealed, aseptic precautions being employed. At each five day interval of storage a flask of the series was opened and the hemoglobin of the plasma estimated. The data are presented in table 3. It will be seen that in each experiment the blood stored with air excluded hemolyzed less rapidly than did the control blood exposed to the air, in the proportion of 1:1.5 up to 1:5. It should be noted, however, that this comparison was always made between fractions of the same blood mixed with the same lot of preservative; the hemoglobin values could not be duplicated in successive experiments, although the same relationship between two fractions of the same blood always held. This suggests either an individual difference between bloods or some slight variation in the preparation of the preservatives which has escaped detection.

The rates of hemolysis were studied in blood mixtures stored in Erlenmeyer flasks in which air of once or twice the volume of the mixture was trapped by closing the flasks tightly with rubber stoppers. Blood stored under these conditions hemolyzed no more

and the other to a suction bulb. After the citrate solution is aspirated through the needle into the dextrose solution and the two are thoroughly mixed, the needle is inserted into the donor's anesthetized vein and the blood is drawn into the mixture by suction, if necessary, the flask being rotated gently to mix the blood and the cold preservative (5 C.). The flask is immediately stored in the refrigerator until required for transfusion, when the blood is thoroughly mixed and passed through a fine wire mesh filter into an arsphenamine tube which is connected by rubber tubing to the needle in the recipient's vein. The blood is not warmed and is allowed to run in by gravity.

Criteria for determining when preserved blood becomes unfit for use cannot be presented accurately. From experience we have adopted the arbitrary rule that citrated blood should be discarded after ten days of storage and blood in the dextrose-citrate mixture is considered unfit for transfusion after thirty days. With this practice there have been no unusual reactions which could be ascribed to disintegrated blood and no hemoglobinuria. The oldest blood used was transfused after storage in dextrose-citrate mixture for thirty-eight days. The recipient suffered no reaction, and no hemoglobin appeared in the urine.

In the operation of a blood bank where the daily number of transfusions is large the need for a preservative in which blood can be stored for more than seven days is not urgent. If the number of transfusions is not large, however, a proportionately larger loss is incurred among bloods belonging to the rarer groups AB and B. In a blood bank which averages four transfusions daily the mathematical probability that a blood of group AB or B will be required within seven to ten days is not great. Therefore any preservative which can prolong the period of potential usefulness of such a blood results in smaller losses.

There is little occasion in civil practice to transport blood considerable distances. However, this is an important problem in modern military medicine. Three facts presented in this paper bear directly on the technic of transportation. In addition to the property of inhibiting hemolysis, the blood-dextrose-citrate mixture protected the erythrocytes from the trauma of shaking better than the other preservatives studied. The fact that flasks closed with rubber stoppers preserved blood as well as those with cotton plugs is a great advantage in designing facilities for transportation. Lastly, in addition to retarding hemolysis, the storage of blood in flasks from which all air is displaced reduces to a minimum the possible trauma by shaking.

CONCLUSIONS

1. Progressive hemolysis occurs in human blood stored in any of the preservatives studied.
2. The rate of hemolysis is much greater when blood is stored at 20 C. than at 5 C.
3. The addition of large quantities of isotonic dextrose solution to blood slows considerably the rate of hemolysis as compared with that in blood stored with little or no added dextrose.
4. The Rous-Turner blood-dextrose-citrate mixture has been so modified that it can safely be given intravenously without discarding the plasma. This modification consists of ten volumes of blood, thirteen volumes of 5.4 per cent aqueous solution of anhydrous dextrose and two volumes of 3.2 per cent dihydric sodium citrate in water.
5. Blood stored in the modified blood-dextrose-citrate mixture will hemolyze only one twenty-fifth to one fiftieth as much in thirty days at 5 C. as will blood in sodium citrate alone or in sodium citrate plus sodium chloride.
6. The blood-dextrose-citrate mixture has proved safe and practical for human transfusions and is of distinct advantage in the operation of blood banks with a small volume of transfusions.
7. Hemolysis is less in blood stored in sealed flasks from which the air is completely displaced by the blood mixture than when the blood is exposed to the air.
8. Blood stored in flasks containing air trapped by rubber stoppers hemolyzes no faster than blood exposed to the air in cotton-plugged flasks.
9. Erythrocytes stored in the dextrose-citrate mixture resist destruction by shaking better than do those stored in sodium citrate alone or in citrate-saline mixtures.
10. The initial hemolysis encountered when blood is drawn into large volumes of preservatives can be prevented if the blood is cooled rapidly and uniformly by mixing it with preservatives which have been previously cooled to about 5 C.

STUDIES ON PRESERVED HUMAN BLOOD

II. DIFFUSION OF POTASSIUM FROM THE ERYTHROCYTES DURING STORAGE

ELMER L. DeGOWIN, M.D.

JOHN E. HARRIS, Ph.D.

AND

E. D. PLASS, M.D.

IOWA CITY

The concentration of potassium in the human erythrocyte is normally from seventeen to twenty times that in the serum.¹ Any change in this ratio occurring during the storage of blood is of clinical interest in view of the well known toxicity of potassium salts injected intravenously. Dulière² noted a progressive increase

Plasma potassium values in various experiments in which blood was stored in several types of preservatives. The observed values are connected with thin solid lines. In all except experiments 1, 2 and 3 the blood was diluted by preservative mixtures approximately in the proportion of ten volumes of blood to fifteen volumes of preservative. In the three instances the plasma mixture was more concentrated, and when recalculation is made for comparison the values are connected with the broken lines. The heavy solid line represents the mean of all the comparable values.

in the plasma potassium of human blood stored for ten days. Jeanneney and his co-workers³ confirmed this observation and also demonstrated a coincidental diminution of plasma sodium.

The studies here recorded were undertaken with the hope that the increase in plasma potassium might serve as an index of corpuscular deterioration. Some of the data were published in a preliminary report⁴ and later presented in an exhibit.⁵ Scudder, Drew, Corcoran and Bull⁶ have since published detailed experiments dealing with the same subject.

METHODS

Blood was drawn aseptically from the median basilic veins of healthy men into pyrex Erlenmeyer flasks of 1,000 cc. capacity containing the preservative solutions. After uniform suspensions had been attained by rotation, each blood mixture was apportioned equally into seven or eight 250 cc. Erlenmeyer flasks, which were stored under identical conditions. For each analysis a flask containing 50 cc. of blood mixture was withdrawn from storage, the contents were thoroughly shaken and

cent sodium citrate (Merck's reagent grade, $\text{Na}_2\text{C}_2\text{H}_3\text{O}_2 \cdot 2\text{H}_2\text{O}$) in water, 0.95 per cent sodium chloride U. S. P. in water and heparin (Connaught Laboratories) in water. These concentrations were considered isotonic because their freezing points were identical with that of blood serum (-0.56°C).

The refrigerator was cooled with salt brine which maintained the temperature between 3 and 5 C. Continuous thermal records were kept. The thick layer of frost on the open refrigeration coils insured a high relative humidity, so that evaporation from the blood mixtures was negligible.

INHERENT ERRORS OF THE PROCEDURE

The values obtained from the specimens in any series may be compared directly because the samples were derived from the same original mixture of blood and preservative solution. In comparing values obtained

centrifuged, and the plasma⁷ was pipetted off for analysis. This procedure insured a constant proportion of cells and plasma in all specimens of a series derived from any initial blood mixture.

Estimations of the plasma potassium were made by the silver cobaltinitrite method of Truszkowski and Zwemer.⁸ Analyses were made in triplicate and were compared with duplicate standards. The deviation from the mean in these determinations was generally less than 2 per cent. The possibility that ammonia contributed to the observed values was excluded by comparing plasma filtrate with ashed samples.

The solutions used were 5.4 per cent anhydrous dextrose U. S. P. (Merck & Co., Inc.) or anhydrous dextrose (Eastman Kodak Company) in water, 3.2 per

cent sodium citrate (Merck's reagent grade, $\text{Na}_2\text{C}_2\text{H}_3\text{O}_2 \cdot 2\text{H}_2\text{O}$) in water, 0.95 per cent sodium chloride U. S. P. in water and heparin (Connaught Laboratories) in water. These concentrations were considered isotonic because their freezing points were identical with that of blood serum (-0.56°C).

The refrigerator was cooled with salt brine which maintained the temperature between 3 and 5 C. Continuous thermal records were kept. The thick layer of frost on the open refrigeration coils insured a high relative humidity, so that evaporation from the blood mixtures was negligible.

The values obtained from the specimens in any series may be compared directly because the samples were derived from the same original mixture of blood and preservative solution. In comparing values obtained from one series with those of another series, however, the method of making the original dilutions must be considered. The preservative solution was accurately pipetted into the receiving flask but, under the clinical conditions of performing venesection, the blood was added to a predetermined mark on the sloping side of the Erlenmeyer flask. The error in measuring 100 cc. of blood by this method was determined experimentally as ± 50 cc., and the coefficient of variation⁹ was calculated as 21.1 per cent. Since this value slightly exceeded the coefficient of variation of the observed maximal values for plasma potassium, it was concluded that the spread of the curves could be accounted for by fortuitous errors in dilution rather than by the other conditions of the experiments.

ANALYSIS OF DATA

The pertinent data are presented in table 1. Since the most common dilution used was ten volumes of blood to fifteen volumes of preservative the observed values in plasma of this mixture are given and the

$$9. \text{Coefficient of variation} = \frac{\text{Standard deviation} \times 100}{\text{mean}}$$

$$\text{Standard deviation} = \sqrt{\frac{\text{Sum of squares of deviations from the mean}}{\text{number of values}}}$$

values in other dilutions were recalculated with a dilution factor to make them directly comparable (experiments 1, 2, 3 and 16).

When the values for plasma potassium are plotted on the ordinate against time of storage on the abscissa (as in the chart) it is evident that under all conditions investigated the rate of diffusion of that ion from the cells was rapid during the first five days, then slowed, and the plasma potassium approached a maximum in about fifteen days.

THE CONTRIBUTION OF HEMOLYZED CELLS TO THE RISE IN PLASMA POTASSIUM

The hemoglobin of the plasma was estimated by the method of Wu,¹⁰ and the values obtained were utilized to determine the proportion of hemolyzed erythrocytes. The high values for plasma potassium could not be explained by the release of potassium from hemolyzed cells. One example will suffice. In experiment 3 hemolysis was much greater than in experiment 5, but the corrected values for plasma potassium show that diffusion of that ion proceeded to approximately the same extent in the two (table 2).

EFFECT OF SODIUM, CHLORIDE, DEXTROSE, CITRATE AND HEPARIN ON POTASSIUM DIFFUSION

The addition of various amounts of sodium, chloride, dextrose, citrate or heparin did not affect the rate of diffusion of potassium from the cells, although some of these substances influenced the rates of hemolysis to a marked degree.¹¹

EFFECT OF ALTERATION OF THE CARBON DIOXIDE TENSION ON POTASSIUM DIFFUSION

Most of the experiments were performed with blood specimens exposed to the outside air through bacteriologic cotton plugs in the flasks, allowing free diffusion of carbon dioxide from the blood and oxygen into the blood. A few studies were made in which different gas tensions were established. In experiments 2, 11 and 13 the blood mixtures were stored with all air excluded. Erlenmeyer flasks of 50 cc. capacity were filled with blood mixtures, and the remaining air was displaced through capillary glass tubes in rubber stoppers. The tubes were then sealed in the flame. This procedure kept the oxygen and carbon dioxide tensions at approximately the original values; thus the carbon dioxide was much greater and the oxygen much less than in blood mixtures exposed to the air. The diffu-

sion of potassium from the cells was not significantly altered by these conditions.

Storage under different atmospheres was also utilized. The blood mixture in experiment 14 was stored with an equal volume of air trapped by a rubber stopper. In experiment 15 the air was displaced by carbon dioxide, in experiment 16 by nitrogen. These conditions did not affect the potassium diffusion.

THE EFFECT OF TEMPERATURE ON POTASSIUM DIFFUSION

In experiments 11 and 12 blood mixtures were stored at room temperature (approximately 20 C.). In one series of flasks air was entirely excluded, while the flasks of the other series were closed with cotton plugs and placed in a pan of water covered by a bell jar to control evaporation. Hemolysis proceeded very rapidly at this temperature¹¹ but the potassium diffusion was not noticeably accelerated.

COMMENT

The data presented agree in general with those reported by Scudder and his associates.⁶ Certain apparent discrepancies may be explained by differences in experimental procedure. The workers just cited stored large amounts of blood mixture in one flask and pipetted off samples of supernatant fluid for analysis. Their method assumes a uniform distribution of potassium throughout the plasma overlying the layer of cells, while the sampling depletes the plasma and makes recalculation necessary to accommodate for changes in dilutions. In the method reported here, all specimens for an experiment were derived from the original blood mixture, stored individually and analyses made on plasma from which the corpuscles had been centrifuged. Thus all samples of a series originally had the same proportion of cells to plasma.

CONCLUSIONS

1. There is progressive diffusion of potassium from human erythrocytes into the plasma during storage.
2. This diffusion is rapid during the first five days but becomes gradually less. A maximum concentration of potassium in the plasma is approached in from fifteen to twenty days.
3. The high values of plasma potassium attained in from fifteen to thirty days of storage cannot be accounted for by the release of that ion from completely hemolyzed cells.
4. Variations in the content of sodium, chloride, citrate and dextrose in the preservative mixtures or storage at different temperatures and in various atmospheres did not affect the diffusion rate.

The Neuroses in Aviation.—Nervous fatigue such as occurs in aviation does not involve functional disorders or disturbances and is readily amenable to rest. There is a point, however, where functional nervous disturbances may make their appearance and an actual neurosis intervene. There are two general types of neuroses which develop in airplane pilots. One type develops in relatively stable individuals, is not necessarily disabling and is an entity seen only among aviators. The other type develops in relatively unstable pilots or in relatively stable pilots under conditions of unusual stress, is disabling, and is identical with those neuroses seen in general practice. The former is known as aeroneurosis, while the latter is composed of the ordinary clinical neuroses which have flying as the principal inciting cause.—Armstrong, Harry G.: Principles and Practice of Aviation Medicine, Baltimore, Williams & Wilkins Company, 1939.

STUDIES ON PRESERVED HUMAN BLOOD

III. TOXICITY OF BLOOD WITH HIGH PLASMA POTASSIUM TRANSFUSED INTO HUMAN BEINGS

ELMER L. DeGOWIN, M.D.
ROBERT C. HARDIN, M.D.
AND
JOHN E. HARRIS, Ph.D.
IOWA CITY

In a previous paper¹ it was shown that some of the potassium in the erythrocytes of human blood diffused out during storage and that the maximum concentration of that ion in the plasma was approached in fifteen days. The rate or the amount of diffusion was not affected by the type of preservative used or the other conditions of storage studied. The question arose as to whether blood stored for two weeks or more would be toxic when transfused into human beings. Some clinical evidence existed indicating that such blood was not harmful, since various workers had occasionally trans-

When Zwemer and Truszkowski⁴ attempted to determine the lethal dose of potassium salts in various animals, intraperitoneal injection was finally adopted, so difficult was it to control the blood level by intravenous administration because of the rapidity of diffusion of the salts into the tissues. To illustrate this fact, one experiment in our laboratory may be cited. Two dogs were selected, each weighing 9.5 Kg. One animal was given an injection of 0.3 Gm. of potassium chloride in the jugular vein. The operation was completed in thirty seconds and the dog died within two minutes from cardiac arrest. The other dog received exactly the same dose of the salt in the same manner except that the time taken for injection was sixty seconds. No abnormal signs resulted, and the animal remained perfectly well. It is therefore evident that in considering the toxicity of potassium from intravenous administration the velocity of injection is an important factor. When a patient receives a transfusion in one median basilic vein it seems that the electrocardiogram would present more direct evidence of potassium toxicity than would estimations of the serum potassium of blood drawn from the other median basilic vein.

fused aged blood successfully before the phenomenon of potassium diffusion was known.

The subject of the toxicity of potassium salts administered intravenously has been reviewed by Scudder, Drew, Corcoran and Bull,² and the reader is referred to their paper for the bibliography. It is undoubtedly true that, if the concentration of potassium in the blood plasma reaching the heart is increased sufficiently, changes occur in the conducting mechanism, which may cause cardiac standstill. Winkler, Hoff and Smith³ demonstrated that isotonic solutions of potassium chloride injected into the femoral veins of dogs cause alterations in the electrocardiogram when the serum potassium attains a concentration of from 5 to 11 millimols per liter and that cardiac arrest results when the level reaches from 14 to 16 millimols.

The object of this study was to ascertain whether preserved blood stored long enough to attain maximum concentration of potassium in the plasma was toxic when transfused into human beings under the usual clinical conditions. From data presented in another study² it was evident that blood must be used which had been stored fifteen days or longer to attain the maximum concentration of plasma potassium. It had also been shown⁵ that a practical method of preserving blood for that length of time without extensive hemolysis was the use of a mixture of ten volumes of blood, thirteen volumes of 5.4 per cent dextrose in water and two volumes of 3.2 per cent dihydric sodium citrate in water. This dilution of the plasma reduced the concentration of the potassium per cubic centimeter by about two-thirds the value obtaining in citrated blood of the same age, but the total amount of the ion in the plasma was approximately the same in the two mixtures since it was derived from the erythrocytes of 500 cc. of blood in both cases. Transfusion of citrated blood stored for fifteen days was considered too dangerous:

because of the high content of hemoglobin in the plasma, but such mixtures stored for ten days were used in some cases since the concentration of potassium per cubic centimeter of plasma was higher than in the more dilute dextrose-citrate mixture.

Fourteen patients requiring transfusions were given preserved blood by the usual technic of intravenous administration. In none was there clinical or electrocardiographic evidence of heart disease. Precautions were taken to insure the urine being alkaline before transfusion by the administration of sodium bicarbonate if necessary.⁶ The blood mixture was allowed to run into the vein of the recipient by gravity. The velocity was varied by adjusting the height of the column of fluid and by using needles of two calibers, 16 gage and 20 gage. The preserved blood was not heated to body temperature before injection.

Immediately before, in the middle and at the conclusion of each transfusion blood specimens were withdrawn from the opposite arm of the recipient. A sample was also taken from the last 20 cc. of transfusion mixture remaining in the apparatus. Quantitative estimations of plasma or serum potassium were made in duplicate on each sample, using both a modification of the silver cobaltinitrite method of Truszkowski and Zwemer,⁷ to be reported later by one of us (Harris), and also the chloroplatinate method of Consolazio and Talbott with slight modification.⁸ The values obtained by the two procedures gave satisfactory checks, so that only the results by the silver cobaltinitrite method are published here.

When the blood samples were withdrawn from the recipient, electrocardiographic tracings were made with the three standard leads. All the pertinent data are presented in the table. No unusual clinical reactions were observed except for the appearance of generalized urticaria in case 1. Electrocardiograms during this transfusion showed tachycardia, which was attributed to the necessary scratching due to the pruritus. In a large series of transfusions of preserved blood no evidence has been obtained to attribute the occasional incidence of urticaria to the high potassium content of the plasma. There were no alterations of the electrocardiograms of the other thirteen recipients during transfusion. The velocity of injection in different experiments varied from 6.6 to 43.3 cc. of blood mixture per minute. Two of the recipients (cases 4 and 13) had slightly elevated initial serum potassium values and one (case 14) had a low level before transfusion. The highest concentration of plasma potassium in transfused blood was 148 mg. per hundred cubic centimeters, and this was given at the rate of 41.6 cc. of blood mixture per minute. The rise in serum potassium of the recipients during transfusion never exceeded 2.2 mg. per hundred cubic centimeters and was not accompanied by any symptoms.

CONCLUSIONS

The high plasma potassium content in blood preserved for thirty days is not toxic when the blood mixture is transfused into human beings at velocities of less than 43.3 cc. per minute. The concentrations of plasma potassium encountered in blood stored for one month are not high enough to cause significant increases in the serum potassium of the recipient.

STUDIES ON PRESERVED HUMAN BLOOD

IV. TRANSFUSION OF COLD BLOOD INTO MAN

ELMER L. DeGOWIN, M.D.

ROBERT C. HARDIN, M.D.

AND

L. W. SWANSON, M.D.

IOWA CITY

It is still common clinical practice to maintain at body temperature fluids which are being administered intravenously. This probably originated from clinical dicta which preceded the fundamental work of Seibert¹ on pyrogenic substances. Seibert demonstrated that certain river bacteria could live in distilled water and produce soluble substances called pyrogens, which were ultrafiltrable and were relatively thermostable. When these substances were injected intravenously into rabbits, febrile reactions ensued. This work has been amply confirmed both experimentally and clinically. Subsequent observations when the presence of pyrogens has been carefully excluded have disproved the theory that the temperature of the fluids is responsible for the production of chills and fever.

Rademaker² reported that intravenous administration to patients of fluids at 20 C. (68 F.) and at 43.3 C. (110 F.) caused no reactions. When cold solutions were given there was a slight drop in the body temperature without chills. Thompson³ stated that injections given at 20 C. (68 F.) and 42 C. (107.6 F.) produced no chills or fever in patients but that cold fluids usually lowered the blood pressure slightly. In an extensive study on rabbits, Banks⁴ not only confirmed the work of Seibert but concluded that solutions administered parenterally at from 68 to 113 F. (20 to 45 C.) had no influence on the body temperature.

A rough calculation can be made showing the effect which the intravenous injection of a cold solution would have on the body temperature if the heat regulatory mechanisms were suspended, and the assumption is made that the thermal capacity of the parenteral fluid is the same as that of the body tissues. A simplified formula expressing the physical principle of equal heat exchanges can then be stated: $M_1(t_1 - t) = M_2(t - t_2)$ where M_1 is the mass of parenteral fluid injected, M_2 the body weight, t_1 the temperature of the fluid, t_2 the original body temperature, and t the resultant temperature of the transfused body. If one takes a specific clinical problem, when 600 cc. of fluid at 5 C. (41 F.) is injected intravenously into a man weighing 70 Kg. and having a temperature of 37 C. (98.6 F.) the following equation results: $0.6(5 - t) = 70(t - 37)$, or $t = 36.72$ C. The body temperature would then be reduced by only 0.28 C.

This conception is of practical clinical importance because considerable labor is expended by the intern and nursing staff and frequently costly apparatus is used in an effort to maintain parenteral fluids at body temperature during injection. When the parenteral

fluid is blood, there is the danger of hemolysis from the injudicious application of heat. Baker⁵ reported a case in which blood inadvertently heated to 130 F. (54.4 C.) produced transfusion anuria. He also pointed out the lack of necessity of heating transfused blood and stated that transfusions were given at room temperature at the Manchester Royal Infirmary with impunity.

The problems introduced by the use of preserved blood for transfusions make imperative a study of the effects of injecting fluids at room temperature or lower. The blood mixtures are usually stored in large flasks in volumes of 500 to 1,000 cc. at 5 C. When the blood mixture is required for transfusion, time may be consumed in warming such a quantity to body temperature or even to room temperature. Moreover, evidence has been presented in another paper⁶ to show that procedures which vary the temperature of different parts of a blood mixture tend to promote hemolysis.

Because of these considerations, a study of the effects of transfusion of unheated blood was made. This study was divided into two parts: first, detailed observations

were made of the recipient's rectal temperature and blood pressure. The data are summarized in table 1.

In conducting this series of experiments the attempt was made to simulate the usual conditions under which this particular apparatus is used and also to produce the extreme variations to which the procedure might be subjected clinically. Thus the minimum temperature of the transfused blood at the recipient's vein ranged in different transfusions from 25 to 15 C. and the velocity of transfusion varied from 6.0 to 42.8 cc. per minute. No clinical symptoms or signs were noted in any of the ten recipients. The rectal temperatures either remained constant or declined a maximum of 0.2 degree C. Patient 7 had fever (initial temperature 101.2 F.), which was not affected by the transfusion. The blood pressure readings varied slightly during the transfusion, but most of the readings were within the limits of error of the method. In case 1 the systolic pressure rose 25 mm. of mercury and the diastolic pressure increased by 10 mm., but the patient was obviously apprehensive. In case 6 the systolic pressure fell 30 mm. and the

* The first value denotes variation in systolic pressure, the second, diastolic.

on ten patients receiving transfusions, and, second, a careful check of all patients receiving transfusions of cold preserved blood in the University Hospitals for a period of eleven months.

Ten patients receiving transfusions were carefully studied. A flask of preserved blood was taken from the refrigerator at 5 C. and within a few minutes was being administered to the recipient. The apparatus used for injection consisted of an arsphenamine tube of 800 cc. capacity communicating with the recipient's vein by about 4 feet of gum rubber tubing, a glass adapter and a needle. The velocity of injection was controlled by varying the height of the column of fluid and the use of either 20 gage or 16 gage needles. The temperature of the transfused blood was observed by inserting a thermometer into the rubber tubing adjacent to the point where the blood mixture ran into the needle in the recipient's vein. The blood mixture was poured into the arsphenamine tube at approximately 5 C., but as it ran through the rubber tubing it approached the temperature of the room. The temperature of the blood at the recipient's vein was thus lower near the beginning of the transfusion and also varied with the velocity of injection. During the transfusion frequent observa-

diastolic pressure 10 mm. This could be accounted for by assuming some initial emotional elevation.

All the patients in the series either volunteered the information, or affirmed when asked, that the vein into which the blood was running felt cool or cold but that this symptom was not such as to cause annoyance. When the blood was injected into the median basilic vein, palpation of the corresponding cephalic vein often gave a sensation of cold to the examiner.

The second part of the study consisted of the application of this method of transfusion of cold preserved blood for routine hospital purposes. In the University Hospitals from Feb. 14 to Aug. 3, 1939, a total of 568 transfusions of cold blood were given by means of the general procedure outlined. The transfusions were administered by many persons and at different velocities with room temperatures varying widely. The blood was usually injected through a 20 gage needle, although smaller needles were used for children. Each recipient was examined within twenty-four hours after the transfusion by an intern attached to the Blood Transfusion Laboratory, who himself tested the urine for the presence of hemoglobin, noted any unusual symptoms during or after transfusion and recorded any elevation of temperature.

The results of these observations are shown in table 2.

Whether any of the reactions reported could be ascribed to the temperature at which the blood was

5. Baker, S. L.: Urinary Suppression Following Blood Transfusion, *Lancet* 1: 1390-1394 (June 12) 1937.

6. DeGowin, E. L.; Harris, J. E., and Plass, E. D.: Studies on Preserved Human Blood. I. Various Factors Influencing Hemolysis, this issue, p. 850.

transfused can be answered only by indirect evidence. The incidence of 8.5 per cent reactions of all varieties seems too small to ascribe to a procedure used in all cases. The hemoglobinuria was adequately explained by other causes in both cases; one patient received incompatible blood and the other was given blood which had a high concentration of plasma hemoglobin. No correlation between the procedure and the occurrence of urticaria could be found.

The presence of pyrogens in the parenteral fluids mixed with the transfused blood and in the apparatus should be considered. All the equipment utilized in the administration of blood and parenteral fluids was prepared in a central laboratory. The fluids for intravenous use were manufactured in the same place, one source of distilled water being used for parenteral fluids, for cleansing apparatus and for blood preservatives. All of

TABLE 2.—Results of Transfusions from Feb. 14 to Aug. 3, 1939

Symptoms	Number	Percentage
No symptoms or signs.....	520	91.5
Chills only.....	6	1.0
Chills and fever.....	31	5.4
Urticaria only.....	8	1.4
Hemoglobinuria.....	2	0.3
Abdominal pain.....	1	0.1
Total.....	568	99.7

these functions were under the same general supervision so that if pyrogens were present in the transfused blood it was to be expected that they would also occur in the parenteral solutions in about the same proportion. This was apparently a fact, although the only data available cover the month of July 1939.

During that period 1,076 intravenous infusions were given at room temperature and in thirty-two cases (2.9 per cent) there were associated chills and fever. For the same time the statistics for transfusions of preserved blood given cold were as shown in table 3.

TABLE 3.—Results of Transfusions During July 1939

Symptoms	Number	Percentage
No reaction.....	103	91.9
Chills and fever.....	7	6.2
Hemoglobinuria.....	1	0.8
Urticaria.....	1	0.8
Total.....	112	99.7

The source of the febrile reactions in both parenteral infusions and blood transfusions is still not explained, but the incidence in either case is so low that it cannot be attributed to the temperature of the fluid administered.

CONCLUSIONS

1. A detailed study of ten patients who were given transfusions of blood mixtures varying from 25 to 15 C. and at velocities from 6.0 to 42.8 cc. per minute revealed no significant lowering in the body temperature, no consistent changes in blood pressure and no untoward clinical symptoms.

2. Preserved blood has been administered without preheating in 568 cases with no reactions which could be attributed to the procedure.

3. The practice of transfusing preserved blood cold is a great convenience in conserving time and prevents untoward reactions involved in the process of heating it.

4. Parenteral fluids other than blood can be administered at room temperature with safety.

STUDIES ON OXYURIASIS

XXII. THE EFFICACY OF GENTIAN VIOLET IN THE TREATMENT OF PINWORM INFESTATION

WILLARD H. WRIGHT, Ph.D.

AND

FREDERICK J. BRADY, M.D.

Chief and Passed Assistant Surgeon, Respectively, Division of Zoology,
National Institute of Health, United States Public Health Service
WASHINGTON, D. C.

The inadequacy of available therapeutic measures for the control of pinworm (*Enterobius vermicularis*) infestation is well known to those physicians who have had experience in dealing with this troublesome problem. In fact, the failure of conventional methods of therapy in these cases is sometimes a source of embarrassment to the physician, particularly when these patients return time after time for further treatment. Unfortunately, either the large majority of the published articles on the treatment of this disease have been based on inadequate numbers of cases or reliance has been placed on the patient's history for the diagnosis and on clinical observations for the efficacy of the treatment.

Undoubtedly the pinworm is the most common and widespread of the animal parasites infesting man in this country. Improvements in sanitation and an efficient meat inspection service have limited the spread of many animal parasites, but modern sanitation has apparently had little effect in limiting the spread of the pinworm. Cram, Jones, Reardon and Nolan¹ have reported an incidence of pinworms of 35.4 per cent in 628 persons from the general population of Washington, D. C. While these cases did not represent a random sampling of the population and the incidence figure in this group is probably higher than is the general incidence figure, yet the latter figure is probably an impressive one.

Prior to the development of the NIH anal swab described by Hall,² there was no efficient method available for the diagnosis of pinworm infestation. Ordinary methods of stool examination, such as are used for the detection of other intestinal parasites, are not of value in the case of the pinworm for the reason that the ova of the parasite are not deposited in the intestinal tract of the host but are expelled by the gravid female worm after its migration out of the anal canal. In this connection, Wright and Cram³ found that only fourteen of 102 known pinworm infestations were detected on stool examination, while Sawitz, Odom and Lincicome⁴ detected 14 and 18 per cent of 131 positive cases by brine and zinc sulfate flotations, respectively, whereas 72 per cent of these positive cases were detected by one NIH swab examination and 99 per cent by seven NIH swab examinations.

The NIH swab consists of a glass rod tipped with a small square of cellophane. This rod is enclosed in

a glass test tube for convenience and for the prevention of infection in handling. In use, the cellophane tip is stroked over the perianal region and pinworm eggs, if present, will usually adhere to the cellophane which may be removed, mounted between a glass slide and coverslip and examined for ova. This method of diagnosis is superior to any other practical method of examination and has been used by us for making diagnoses and for checking the efficacy of treatment.

Another important fact disclosed by investigations in our laboratory has been that relating to the frequent occurrence of familial pinworm infestations. Wright and Cram³ have pointed out the necessity from a control standpoint of treating pinworm infestation on a familial basis on the ground that it is useless to treat individuals in a family or household in which other individuals, infested with pinworms, are left untreated. The abundant opportunities for reinfestation in such households are indicated by the results of Reardon⁵ of egg counts in twenty gravid female pinworms in which the mean of the counts was 11,105 and by the experience of Nolan and Reardon,⁶ who were able to recover pinworm ova from objects at all levels in all rooms in infested households thus indicating the possibilities of airborne infections. In view of the practical impossibility of applying hygienic measures in a manner sufficiently rigorous to control pinworm infestations, the use of chemotherapy would appear to be necessary in most cases for the successful attack on this parasite.

EFFICACY OF OTHER METHODS OF THERAPY

In experiments in this laboratory, single-dose treatments with tetrachlorethylene or hexylresorcinol orally have not proved satisfactory. While tetrachlorethylene is probably the most effective of the available single-dose treatments, as shown by Wright, Bozicevich and Gordon,⁷ it is not sufficiently effective to be of value in the treatment of familial pinworm infestations. Under certain conditions of temperature and moisture, pinworm eggs may remain viable in the laboratory for two weeks or longer. If the ova are equally resistant under household conditions, patients freed of pinworms by a single-dose treatment may be subjected to frequent reinfestation over this period of time.

These facts led Wright, Brady and Bozicevich⁸ to a search of some method of treatment which could be administered over a period of time sufficient to allow for desiccation of the pinworm ova in the patient's surroundings, with a view of eliminating the possibilities of reinfestation. Santonin, one of the few known anthelmintics which can be given with safety in repeated treatments, was not found sufficiently valuable to warrant its use in this connection. Only eleven, or 55 per cent, of twenty cases treated with santonin over a period of ten days were negative on post-treatment swab examinations. As an inadequate number of post-treatment swabs was obtained in some of these cases, it is probable that the efficacy of the treatment was actually at the rate of less than 50 per cent. Hexylresorcinol enemas, first used by Brown,⁹ have proved

relatively effective when compared with many other methods of treatment. Of twenty-seven cases in which such enemas were used, eighteen, or 66 2/3 per cent, were negative on post-treatment swab examinations. The chief objections to the use of hexylresorcinol enemas are those concerned with the high cost of the drug and the labor in administering the treatment to several individuals in the family at the same time. For these reasons this treatment is not adapted for general use in familial infestations. The routine treatment with hexylresorcinol orally and by enema, as recommended by Craig and Faust,¹⁰ has been used in a few cases but not one of the individuals was freed from pinworms by this method of therapy.

Experience with the experimental use of the aforementioned methods of therapy led us to the view that a satisfactory treatment for pinworm infestation should fulfil certain specifications, as follows: 1. The drug should be sufficiently safe that it can be administered in repeated treatments over a period of time. 2. It should be highly effective. 3. It should be of reasonable cost. 4. It should be of such a nature that it can be easily administered and used with a minimum of effort in large families in which many persons are infested.

As none of the traditional methods of therapy which we had tested entirely fulfilled these specifications, we have carried out tests with gentian violet, one of the few known anthelmintics which can be given with safety in repeated treatments over a period of time.

PREVIOUS USE OF GENTIAN VIOLET

Our application of gentian violet in the treatment of oxyuriasis followed the employment of the drug in a number of other conditions. Young and Hill,¹¹ who were apparently the first to use the dye medicinally, employed doses of from 5 to 7 mg. per kilogram of body weight administered intravenously for the treatment of septicemia and local infections. Later, Faust and Yao¹² employed gentian violet orally and intravenously in the treatment of *Clonorchis sinensis* infestations. However, the drug has been used more extensively for *Strongyloides stercoralis* infestation than for any other parasitic condition. Sioe's¹³ report on the use of the dye in this condition was followed closely by that of de Langen;¹⁴ in addition, the experiments of Faust¹⁵ added considerably to our knowledge of the value of the drug in strongyloidosis.

EXPERIMENTAL PROCEDURE

Prior to treatment for pinworms, a clinical history was obtained and a physical examination made on each patient to ascertain whether any contraindications existed for the treatment. In addition to the diagnostic NIH swab examinations, a stool specimen from each patient was examined by one of the flotation techniques. When the stool examination showed eggs of *Ascaris lumbricoides*, the patient was treated for the removal of this parasite before gentian violet was prescribed.

9. Brown, H. W.: Treatment of Pinworm (*Enterobius Vermicularis*) Infestation with Hexylresorcinol, *Proc. Soc. Exper. Biol. & Med.* 30: 221-224 (Nov.) 1932.

In order to check the efficacy of the treatment, seven consecutive daily NIH swabs have been made beginning at certain intervals after the completion of the treatment. Cram, Jones, Reardon and Nolan¹ have shown that six such swab examinations will detect nearly all pinworm infestations, while the work of Sawitz, Odom and Lincicome⁴ confirmed these observations and indicated that seven NIH swab examinations will disclose over 99 per cent of the positive cases. In the absence of precise information on the prepatent period of the pinworm, *Enterobius vermicularis*, the timing of these swabs has been based largely on the results of the self-infestation experiments of Leuckart,¹⁶ Grassi¹⁷ and Calandruccio,¹⁸ these experiments indicating apparently that gravid females of *E. vermicularis* begin to migrate between the fourteenth and the twenty-first day after infestation. On the basis of this evidence, the post-treatment swabs were started in a large number of patients on the tenth to the fourteenth day after the end of the treatment.

TREATMENT WITH ENTERIC COATED GENTIAN VIOLET TABLETS N. N. R.

In a preliminary communication, Wright, Brady and Bozicevich¹⁹ reported on the treatment of a total of 163 patients with enteric coated gentian violet tablets N. N. R., the post-treatment checks being made by means of seven consecutive daily NIH swabs beginning on the tenth to the twenty-first day following the end of treatment. The daily dosage of gentian violet prescribed for adults was that used by Faust²⁰ and for children that used by Kouri, Sellek and Rivera²¹ in the treatment of *Strongyloides stercoralis* infestations. Adults received two 32 mg. (one-half grain) tablets before meals three times daily. Individuals 16 years of age and younger received approximately 10 mg. a day for each year of apparent (not chronological) age. Thirty-six of the 163 patients were classed as non-cooperative, since they either failed to complete the treatment or failed to furnish post-treatment swabs; five patients were advised to discontinue treatment because of reactions that were due, in part at least, to the gentian violet therapy. Of the remaining 122 individuals 107, of whom eighty-five were under 16 years of age and twenty-two were over this age, were given the drug in daily doses over a period of ten days, while the remaining fifteen individuals, all children, received the drug over a period of eight days, were allowed to rest for seven days and were then treated for an additional period of eight days. A total of 112, or 92 per cent, of these 122 completed cases were negative on the post-treatment swab examinations. All of the fifteen patients receiving the divided course of treatment were negative.

Another series of patients comprising twelve children and three adults has completed treatment since the foregoing cases were reported. These patients were treated with the same dosage of the same type of tablet admin-

istered in two courses of eight days each with a week's interval between courses. Twelve, or 80 per cent, of the fifteen cases were negative on the post-treatment checks taken from fourteen to twenty-one days after completion of the treatment.

As opportunity presented itself, we continued observations on some of the negative patients over longer periods of time. Nineteen patients, mostly boys in an institution, were selected for a further check on freedom from infestation at intervals varying from seven weeks to thirty-four weeks following the end of treatment. The results of a recheck with seven additional daily post-treatment swabs indicated that fifteen of the nineteen individuals were still negative for pinworm ova at the aforementioned intervals after treatment. This result, as we were to learn later, was considerably better than that obtained when noninstitutionalized individuals were checked with post-treatment swabs beginning with the forty-second day after the end of the treatment.

In addition to this check, we kept under continuous observation for periods varying between thirty-eight and fifty-three days after the end of treatment four patients who were swabbed either once or twice a day during this time. At the end of these periods these patients were negative for pinworm ova on swab examinations.

The necessity of checking the validity of our assumption that the life cycle of the pinworm requires from fourteen to twenty-one days became apparent as the experiments progressed. If the parasite actually requires more than twenty-one days to develop to maturity, negative swabs taken prior to that time might give false information. Under such circumstances, young larvae not removed by the treatment might develop to maturity and ova from migrating worms would be deposited after the last swab examination had been made. Thus, in order to add to the critical value of our post-treatment checks, the post-treatment swabs on the remaining patients were started on the forty-second day after the end of the treatment.

Naturally, the prolonged time element in this type of experiment with patients over whom we could exercise no semblance of control adds considerably to the possibilities of reinfestation, since these patients were not hospitalized individuals but were outpatients who carried on their usual duties and maintained the customary routine of their lives. No doubt many of them were subjected to reinfestation with pinworm ova and possibly some of them acquired a reinfestation, in which event the positive observations on the post-treatment swabs would not indicate failure of the treatment. The longer the period between the termination of the treatment and the post-treatment swabs, the more likelihood there would be that positive results indicated a reinfestation and not failure of the treatment.

Further treatment with enteric coated gentian violet tablets N. N. R. was carried out on nineteen additional patients (fourteen children and five adults) and for these patients the post-treatment swabs were started on the forty-second day following the completion of the treatment. These patients were given the same course of treatment, i. e. the gentian violet was administered in the same dosage as used previously and was given over a period of eight days, stopped for seven days and then repeated for an additional period of eight days. Of the nineteen patients eleven, or 58 per cent, were negative on the post-treatment swabs.

TREATMENT WITH GENTIAN VIOLET TABLETS PROVIDED WITH A WATER SOLUBLE COATING

During the course of our experiments it had been occasionally reported to us that the stools of certain patients were not consistently colored by the dye during the course of treatment. In order to check on the disintegration of the tablets, all stools passed by five patients during the course of treatment were screened and it was found that these patients occasionally passed whole or incompletely disintegrated tablets.

As a result, we were interested in the suggestion of Dr. John F. Kessel that we try a tablet provided with a new type of water-soluble coating. Since Dr. Kessel's suggestion, the effectiveness of the new type of coating from the standpoint of timed disintegration of the tablets in the small intestine has been demonstrated radiographically by Worton, Kempf, Burrin and Bibbins.²²

The coating in question consists of the following ingredients in the proportions named: stearic acid 55.5, carnauba wax 24.25, petrolatum 1.75, powdered agar 13.9 and powdered elm bark 4.6.

Gentian violet tablets furnished us by the manufacturer were provided with coatings which permitted disintegration in two and one-quarter, four, four and one-half and five hours, respectively. Worton and his associates noted that the four and five-hour coated tablets invariably opened in the small intestine. We have found the four and one-half hour coated tablets to be as effective as any of the others and have prescribed tablets with this coating for persons of all ages. The preliminary results of these experiments were reported by Wright and Brady.²³

A total of 121 persons have been treated with gentian violet tablets with the water soluble type of coating. Of these, fifty-three cases were incomplete, the remaining sixty-eight persons (fifty children and eighteen adults) having taken the prescribed number of tablets and having furnished the required number of post-treatment swabs. The dosage of gentian violet for these cases was the same as that employed in the use of the enteric coated tablets. However, in this case the tablets were given one hour before meals. The treatment regimen consisted of two periods of eight days each, separated by a rest period of seven days. Seven consecutive daily swab examinations on these sixty-eight persons beginning on the forty-second day after the completion of the treatment showed fifty-four, or 79 per cent, to be freed from pinworms.

REACTIONS ENCOUNTERED IN THE GENTIAN VIOLET TREATMENT FOR PINWORMS

We have encountered similar untoward effects with both types of tablet used in these experiments. A total of 182 patients took the entire course of treatment with the enteric coated tablets, although only 156 (shown in the table) furnished the required number of post-treatment swabs. Of the 182 patients, 114 noticed no ill effects from the treatment. In the remainder, untoward symptoms occurred in the form of nausea thirty-four times, vomiting twenty-nine, diarrhea eighteen, constipation two, headache one, dizziness three, lassitude two and mild abdominal pain twenty-one. A total of eighty-eight patients completed

treatment with the water soluble type of tablet, although only sixty-eight furnished the necessary number of post-treatment swabs. Of the eighty-eight patients fifty-one had no ill effects from the drug. In the remainder nausea was encountered twenty times, vomiting eleven, diarrhea nine, constipation two, dizziness one, lassitude one and mild abdominal pain eleven. Three patients suffering, respectively, from cholecystitis, ear sickness and whooping cough reported vomiting. These cases are not included in the foregoing summary although the gentian violet may have been an aggravating factor in bringing on the vomiting.

All the reactions encountered may be attributed to an irritation of the gastrointestinal tract from the drug, although the symptoms of headache, dizziness and lassitude may have been due to some absorption of the drug. In a dog given 35.4 mg. of gentian violet daily for each kilogram of body weight we were able to recover from the urine on the twelfth to fourteenth days a small amount of a red substance that gave

Summary of Results of Treatment in 224 Cases of Oxyuriasis with Gentian Violet Tablets Administered Orally

* Fifteen of nineteen cases in this series were negative on ^{seventy} additional post-treatment swabs taken at intervals of seven to thirty-four weeks after the end of the treatment.

† Treatment was discontinued for one week between courses.

chemical reactions of a rosaniline derivative. Similar occurrences have never been noted with patients treated for pinworms. The pigment noted in the sections of the liver, spleen and kidneys of experimental animals treated with relatively large doses of the drug may have been due to absorbed dye. However, there has been no evidence to indicate that an appreciable amount of the dye is absorbed with the dosage used in the treatment for pinworms. It was observed that many of the patients having reactions had ill effects during the first several days of treatment. Many of these individuals were able to complete the treatment without further reaction even though there was no reduction in the dosage of the drug. In some cases it was necessary to withhold treatment for a day or two or to reduce the dosage until the reactions subsided. All reactions were temporary in nature.

CONTRAINDICATIONS FOR GENTIAN VIOLET THERAPY

It has been our practice never to use gentian violet treatment for pinworm patients having a concomitant infestation with *Ascaris lumbricoides* until removal of the ascarids. Little is known concerning the action of the drug on this parasite and we feared possible intestinal obstruction from the clumping of ascarids, such as has been reported with some other anthelmintics. We have not used gentian violet for cases in which

22. Worton, A. G.; Kempf, G. F.; Burrin, P. L., and Bibbins, F. E.: A New Enteric Coating and a Laboratory Method for Its Control, *J. Am. Pharm. A.* 27: 21-28 (Jan.) 1938.

23. Wright, Willard H., and Brady, Frederick J.: The Treatment of Oxyuriasis with an Improved Type of Enteric Coated Tablet, *J. Parasitol.* 24 (Supp.): 9-10 (Dec.) 1938.

there might be cardiac, hepatic or renal disease of an appreciable degree. Disease of the gastrointestinal tract is considered also to be a contraindication for gentian violet therapy. Abstinence from alcohol is recommended during the period of treatment. While in our experience small children have not reacted poorly to gentian violet, we have had a few cases of children under 3 years who have been unable to swallow the tablets without rupturing the coating. In these cases we have had to resort to the use of enemas for the treatment of the pinworm infestation.

THE TOXICITY OF GENTIAN VIOLET

Faust²⁰ noted that man and laboratory animals could tolerate daily oral doses up to 35 mg. per kilogram of body weight. The number of such doses tolerated was not stated.

We have given gentian violet in gelatin capsules orally to fifteen rabbits and found the minimum lethal dose for this short series to be 22 mg. per kilogram of body weight given daily for six days. A dog given gentian violet in enteric coated tablets in a daily dose of 35.4 mg. per kilogram of body weight survived treatment for eighteen days; another dog given 40.1 mg. of gentian violet per kilogram daily died after eighteen days of dosing. The maximum dose used for the treatment of pinworm infestation is about 3.5 mg. of gentian violet per kilogram of body weight daily for a total of sixteen days with a week's rest between two eight-day courses. This amount is about one sixth of the minimum dose causing death in rabbits given the drug in gelatin capsules and about one tenth that for dogs given the dye in enteric coated tablets.

In laboratory animals, gentian violet intoxication is manifested by anorexia, vomiting and diarrhea. With severe intoxication, these symptoms are followed by apathy and death. In the dog given 35.4 mg. of gentian violet per kilogram of body weight the erythrocyte count increased from 4,790,000 to 6,930,000 cells per cubic millimeter, the leukocyte count dropped from 23,200 to 12,450 cells and the differential count remained about the same throughout the experiment with from 65 to 74 per cent neutrophilic polymorphonuclear leukocytes. In the dog dying after eighteen days of dosing with 40.1 mg. of gentian violet per kilogram of body weight daily, the blood nonprotein nitrogen remained within normal limits until three days before death, when it began to rise rapidly.

Experimental animals given gentian violet were grossly normal at autopsy except for a moderate congestion of the intestinal mucosa and evidences of dehydration. Microscopically the liver and spleen of our experimental animals generally showed a moderate degree of congestion and in most cases the cells in the liver, spleen and kidneys showed the inclusion of a granular pigment; several animals showed a slight hydropic degeneration of the epithelium of the convoluted tubules of the outer renal cortex.²¹

COMMENT

The accompanying table presents the results of the 224 cases comprising the various series of treatments. It will be seen that there was practically no difference in the percentage of efficacy between the ten-day treatment and the sixteen-day treatment with post-treatment swabs taken between the tenth and twenty-first days after the end of treatment in the former and between the fourteenth and twenty-first days in the latter.

Theoretically it might be expected that the sixteen-day treatment would result in a greater percentage of cures for the reason that the total period covered is twenty-three days, including the seven-day rest period between courses. Compared to the ten-day treatment period, this period would provide more time for the desiccation of ova in the patient's surroundings and reduce the chance of reinfestation. It is possible that a larger series of cases treated over a period of sixteen days might show an advantage in this regimen over that of the ten-day treatment.

The efficacy of the enteric coated tablets in nineteen cases in which post-treatment swabs were started on the forty-second day after the end of the treatment was only 58 per cent. We have discussed previously the possibility of reinfestation in these cases and it seems probable that some of the positive cases may represent reinfestations.

A total of fifty-four, or 79 per cent, of sixty-eight cases treated with the water soluble coated tablets were negative on post-treatment swab examinations. In all these cases, these swabs were taken between the forty-second and forty-eighth days after the end of the treatment. The efficacy of these tablets may thus be compared directly with that in the nineteen cases treated with the tablets provided with the enteric coating. The comparison would appear to be favorable to the former type of tablet. However, critical consideration of the data indicates that the chance variations in the two percentages of efficacy overlap; consequently a comparison would have to be based on a much larger series of cases in the two groups before valid conclusions could be drawn.

There is no practical method for determining the degree of infestation in pinworm cases, and the NIH swab gives no clue as to the number of worms harbored. However, impressions of the degree of the infestation are gained by the history of the frequency of migrations and the number of swabs found positive in a long series. With these impressions in mind, it has appeared to us that the persons with lighter degrees of infestation are cured more easily than those harboring large numbers of pinworms, a number that may reach into the thousands. Theoretically, heavy pinworm infestations would involve the presence of large numbers of developing larvae in the upper intestinal tract. These larvae are more difficult to remove than are adult worms and it appears that some of the failures of gentian violet to eradicate heavy pinworm infestations are due to the failure of the drug to remove the numerous developing forms.

SUMMARY

Experimental treatment with gentian violet administered in repeated oral doses has been completed on a total of 224 individuals; these patients were treated on a familial basis, each member of the family having been examined for pinworms and all infested individuals having been treated simultaneously with the view of eliminating at one time all sources of infestation within the household. A case history was obtained and a physical examination made on each individual to determine whether contraindications for the treatment were present. Pinworm diagnoses were made by means of the NIH cellophane tipped anal swab, while examinations for other helminth ova were made on stool samples by means of one of the flotation techniques. The dosage of the drug for adults was two 32 mg. tablets three

²¹ Dr. L. L. Ashburn, Passed Assistant Surgeon, Division of Pathology, National Institute of Health, made the pathologic examination of this material.

times a day before meals and for children 10 mg. a day for each year of apparent (not chronological) age, the total daily amount of the drug for children being divided also into three doses. The efficiency of the treatment was checked by the use of seven consecutive daily NIH post-treatment swabs. The patients were treated in four series, as follows:

One series of 107 patients received enteric coated gentian violet tablets N. N. R. daily for a period of ten consecutive days. Post-treatment swabs taken in these cases from ten to twenty-one days after the completion of the treatment indicated that ninety-seven, or 91 per cent, were negative for pinworms.

Thirty patients were treated with enteric coated tablets over a period of eight days, were allowed to rest for seven days and were then treated for an additional period of eight days. Of these thirty patients twenty-seven, or 90 per cent, were negative on post-treatment swab examinations taken between the fourteenth and twenty-first days following the end of the treatment.

The third series involved the treatment of nineteen individuals with enteric coated tablets over a period of sixteen days with a week's rest between the eight-day treatment periods. Of these patients eleven, or 58 per cent, were negative on post-treatment swab examinations made from the forty-second to the forty-eighth day following the end of the treatment.

In the fourth series sixty-eight patients were treated with gentian violet tablets provided with a water soluble coating designed for disintegration in the small intestine at approximately four and one-half hours after administration. These patients were given the sixteen-day treatment with the usual seven days rest period between two eight-day courses. The tablets were given one hour before meals. Fifty-four, or 79 per cent, of the sixty-eight patients were negative for pinworm ova on seven consecutive daily post-treatment swabs taken from the forty-second to the forty-eighth day following the end of the treatment.

A certain percentage of the treated patients suffered reactions in the form of nausea, vomiting, diarrhea and abdominal pain but the reactions were of a temporary nature and quickly subsided when the dosage of the drug was reduced or the treatment was discontinued for a period of a day or two.

Contraindications for the use of gentian violet include concomitant infestations with *Ascaris lumbricoides*, moderate to severe cardiac, hepatic or renal disease, alcohol and diseases of the gastrointestinal tract.

The minimum lethal dose of gentian violet for rabbits was 22 mg. per kilogram of body weight daily for a period of six days. One dog tolerated a dose of 35.4 mg. per kilogram daily for eighteen days. No pathologic tissue changes have been found to account for the death of experimental animals succumbing to the administration of gentian violet.

Gentian violet was found to be eminently superior to some and superior to all the other methods of therapy tested under similar conditions and checked by the same technic. Because of its relative cheapness, its ease of administration and its relatively high degree of efficacy, the drug is apparently of greater value than are other known drugs for the treatment of pinworm infestation in families in which many individuals may be infested and in which simultaneous treatment of all infested individuals appears to be necessary for the control of the condition.

Clinical Notes, Suggestions and New Instruments

A GREAT CRAVING FOR SALT BY A CHILD WITH CORTICO-ADRENAL INSUFFICIENCY

LAWSON WILKINS, M.D., AND CURT P. RICHTER, Ph.D.
BALTIMORE

Special food cravings or aversions have received only passing interest in modern medicine and have been almost entirely neglected in modern nutrition. This is due to the prevalent view that appetite cannot be trusted as a guide to the proper selection of foods. Results of experiments on rats using the self-selection technic indicate, on the contrary, that a very close relationship exists between appetite and nutritional needs of minerals and vitamins, as well as of fats, carbohydrates and proteins. In human beings there are only a few instances which throw light on the relationship between appetite and dietary needs. Davis¹ reported that when very young normal children were given free access to a large number of natural foods they made selections which resulted in normal growth and development. She also reported that a child with vitamin A deficiency took large amounts of cod liver oil and thereby caused the deficiency symptoms to disappear.

During the past year we had occasion to make in this hospital a clinical observation which demonstrates in a very striking way the close relationship between appetite and nutritional needs. The endocrinologic aspects and the full medical history of this case have been reported in detail by Wilkins, Fleischmann and Howard.² The following data were taken from their history:

REPORT OF CASE

D. W., a boy aged 3½ years, admitted to the Harriett Lane Home for Children, showed a marked development of his secondary sex organs. His penis and testes were as large as those of a 12 year old boy. The prostate was fairly well developed; spermatogenesis was absent. Over the pubis there was a rather abundant growth of long dark hair. The voice was deep and the laryngeal cartilage was as prominent as that of a full grown man.

The skin on his scalp and body had a slightly brownish hue; the alveoli of the nipples were pigmented and the gums over the upper incisors showed a patch of brownish pigmentation.

His blood had a low sodium and a high nonprotein nitrogen content. Other physical observations were negative.

In the hospital the boy did not seem to be especially ill. He behaved like a very defective child, growling and snarling in an incoherent manner when attempts were made to examine him. He was offered the regular ward diet. His appetite was poor and he ate but little of the food. When feedings were forced, he vomited on several occasions. Seven days after admission he suddenly died.

Postmortem examination revealed that both adrenals were large. There was hyperplasia of the androgenic or prenatal zone cells, with marked diminution of the normal cortical cells. The testes were composed of similar cells crowding out the seminiferous tubules. Otherwise no pathologic changes were found. The precocious development of the secondary male sex characteristics was thought to be due to the embryonic hyperplasia of the androgenic zone of the adrenal. It appeared that death from adrenal insufficiency resulted from destruction of the electrolyte-controlling elements of the adrenal cortex.

One of the interesting features of this case was the presence of a great craving for salt. After his death it was learned that from the age of 12 months the child had eaten salt in large quantities. In addition, he had been given saline enemata

These observations form part of a study of the "Influence of Hormones on Appetite," supported by the Committee on Research in Endocrinology of the National Research Council.

every second or third day because of constipation. Subsequently a full account was obtained from the parents concerning the onset and development of this craving. The following letter, which is one of the most extraordinary documents on behavior on record, was written by the parents in response to a few questions regarding their child's special appetites:

"Dear Dr. —:

"Since receiving your letter it has been on my mind constantly to remember as nearly as possible the correct answers to all of your questions. We want to thank you for your very nice letter and are glad to help in any way we can.

"Some of the things I am writing you I know are not direct answers to your questions, but indirectly I feel that they may be of some help to you and perhaps explain how we had studied D— and his peculiarities. Of course, in the beginning we knew that he was very sick, but did not know his true condition or what to expect.

"We had such a hard time trying to find milk to agree with him that I remembered exactly when each kind was changed; but when he first started eating salt I didn't think it was so important until later when he started craving it.

"With his feeding problems we only gave one new food at a time and took particular notice of the reaction it had on him. At six months we still didn't have any one milk to agree with him for any length of time except mother's milk. At this time Dr. — told us to start giving him strained vegetable soup and beef broth. He liked it, but as soon as it touched his tongue he would gag and bring up everything he had in his stomach unless I made it very thin with the beef broth. About a month later we started giving him strained vegetables; but, no matter what it was, he would bring it all up immediately unless it was very thin, practically liquid. At this time the doctor told us to give him crackers and zwieback; but as soon as he got any crumbs or little pieces of food on his tongue he would gag and bring up everything else. I would keep trying him from time to time thinking that perhaps the next time he would do better.

"When he was around a year old he started licking all the salt off the crackers and always asked for more. He didn't say any words at this time, but he had a certain sound for everything and a way of letting us know what he wanted. This was the first we had noticed his wanting the crackers or salt. Finally he started chewing the crackers; but he only chewed them until he got the salt off, then he would spit them out. He did the same with bacon, but he didn't swallow the pieces. When he was about sixteen months old, crackers were the first food he chewed and swallowed; but it was quite a while after that before he would chew up and eat a whole cracker. He would usually just make a mess of them eating the salt off.

"In an effort to try to find a food that he would like well enough to chew up and swallow, we gave him a taste of practically everything. So, one evening during supper, when he was about eighteen months old, we used some salt out of the shaker on some food. He wanted some, too. We gave him just a few grains to taste, thinking he wouldn't like it; but he ate it and asked for more. This was the beginning of his showing that he really craved salt, because this one time was all it took for him to learn what was in the shaker. For a few days after that, when I would feed him his dinner alone at noon, he would keep crying for something that wasn't on the table and always pointed to the cupboard. I didn't think of the salt, so I held him up in front of the cupboard to see what he wanted. He picked out the salt at once; and in order to see what he would do with it, I let him have it. He poured some out and ate it by dipping his finger in it. After this he wouldn't eat any food without having the salt, too. I would purposely let it off the table and even hide it from him until I could ask the doctor about it. For it seemed to us like he ate a terrible lot of plain salt. But when I asked Dr. — about it, he said, 'Let him have it. It won't hurt him.' So we gave it to him and never tried to stop it altogether. After we gave it to him all the time he usually didn't ask for it with his dinner; but he wouldn't eat his breakfast or supper without it. He really cried for it and acted like he had to have it. Foods that he ordinarily wouldn't touch he would eat all right if I added more salt to them. He would take the shaker and pour some out on his plate and eat it with his finger, but we always tried to keep him from getting what we thought would be too much for him. He never did care much for zwieback, toast or bread or for cooked potatoes, but he did like raw potatoes, raw carrots, celery, tomatoes, lettuce and different other foods if he could dip them in salt. If I didn't give it to him, he always asked for it. At eighteen

months he was just starting to say a few words, and salt was among the first ones. We had found that practically everything he liked real well was salty, such as crackers, pretzels, potato chips, olives, pickles, fresh fish, salt mackerel, crisp bacon and most foods and vegetables if I added more salt. We never tried to force him to eat a food; I always tried to prepare the same food in a way that he would like it. Spinach and green beans were his favorite vegetables. By letting him taste different foods he learned to like quite a variety, although he was three years old before he really ate a good meal by chewing it and swallowing it. In the meantime, I kept feeding him strained foods with the beef broth. . . . As he grew older and ate better, he very seldom brought up his meals any more. But he always wanted a lot of vegetable juice on his foods before he would eat them. If I didn't give it to him, he would ask for it and would eat everything good; but he wanted the salt too. By the time he was three years, I could reason with him and make him understand when he had enough of anything. At the time we had no idea as to the amount of salt he ate, or what the result would be if he didn't have it; but we have measured it now and would say that he ate between three quarters to one teaspoon of plain table salt a day in addition to all his foods being saltier than ours. If he ate a food without it, I let him go; but if he wanted more salt in it, I added a little more. Many times I tried to make him think I added it, but he always knew the difference with the first taste. Some days he may have had a little more or less than the amount stated, which is, as we would judge, the average.

"He would not eat anything sweet, though. Mostly everything with much sugar in it he would either bring back up or just *wouldn't eat it*. He would not eat cereal with sugar and milk on it. I would always strain his cereal into his glass of milk and let him drink it. Wheaties, or any small amount of dry cereal I tried to give him, he would not eat with sugar and milk but wanted it dry with salt sprinkled on. He *did not* like candy, cake, custards, puddings, etc. He did eat a little ice cream or jello.

"He was a very observing baby and, even in his sickly condition, started noticing pictures in books when he was six months old. He always liked books, and we would read to him quite a lot. When he was about two years old he began reading the pictures himself. He would get out one book after another and never seemed to grow tired of reading them. Many times he surprised us by knowing and recognizing things in the pictures we hadn't even noticed. And by the time he was three and a half he knew a few words by sight. When he was two and a half he loved to hunt for the attractive pictures of the good foods in the magazines. He learned to know what all the foods were and made believe he ate them. It was surprising to us to see how this improved his appetite at meal time, for it was at this time that he started chewing his foods better and acted like he really enjoyed them. Another thing that helped him learn to eat was because he became interested in cooking. Many times he would play for an hour or more making believe he was cooking his Daddy's supper and imagining all kinds of foods he was cooking.

"There was no other one food that he seemed to crave like salt, except water. Many people seemed to think this was because he ate so much salt, but he liked lots of water to drink from the time he was four months old. At six months, if we showed him a bottle of water and one of milk, he would take the water in preference to the milk *every time*. And in studying him, we found that by giving him lots of water he would be able to belch easier and so keep his milk down better. He learned to know himself that it helped him. As soon as he knew what the word 'water' meant, he would cry for it every time he heard the word mentioned. And when he saw the river or the ocean, he always thought he had to have some to drink until we were finally able to explain to him that it wasn't drinking water. But up until the time we took him up there he still wanted water every time he saw anybody else drink it. He always asked for it many times between meals; and if there was water on the table at meal time he would rather drink it than eat his meal. And if we let him drink and eat too much without making him stop to belch in between, his food would come back up almost every time. Also, if we let him cry much, he could not keep anything in his stomach.

"At home he acted and played the same as any perfectly normal child. But the doctor had told us not to take him anywhere among people because of contracting contagious diseases, which he didn't think D— could pull through. The result was that he was afraid of strangers; and when we brought him up there it was the first time that he was among

complete strangers and strange surroundings. We had never been away from him ourselves before. Either my husband or I were always with him to take care of him.

"I hope that I have answered all of your questions satisfactorily and also that at least part of what I have written will be of some help to you. In order to remember the answers as nearly correct as possible, it was necessary for me to recall D—'s whole life. If there is anything at all that I have omitted don't hesitate to let us know. We will be glad to answer it if we can. As for the different kinds of milks we gave him and the age when each one was changed, also his growth and development, I had those recorded on the backs of the pictures I sent you sometime after we returned from up there.

"Hoping we have been able to help you in your studies and perhaps some children in the future, we are,

"Yours very truly,

"MR. AND MRS. —."

COMMENT

The full significance of the craving for salt by this child can be obtained from a review of our knowledge of salt craving by adrenalectomized animals.

It is well known that in rats kept on the ordinary stock diets symptoms of insufficiency develop and the rats die within ten to fifteen days after adrenalectomy. Death occurs largely because of the excessive loss of sodium chloride in the urine and the resulting changes in the internal osmotic conditions.³ It is known that the survival time can be increased and the mortality rate decreased by increasing the salt content of the food until it approximates the amount of salt lost in the urine. Further, it was shown that when adrenalectomized rats have access to salt in a container separate from the food they will ingest large amounts of salt and, as a consequence, keep themselves alive and free from symptoms of insufficiency.⁴ Some of the rats ingested from fifteen to twenty times as much of a 3 per cent salt solution thirty days after adrenalectomy as they had in the last ten day preoperative period. That the increased salt appetite depended on the loss of the adrenals was demonstrated by the observation that adrenals successfully implanted to the anterior chamber of the eyes caused the craving to disappear entirely.

This increased craving for salt manifested by adrenalectomized rats is not an isolated instance of a mineral or food craving which is closely related to dietary needs. We⁵ have reported that parathyroidectomized rats have an increased appetite for calcium, magnesium and strontium salts, which are known to decrease parathyroid tetany, and that they have a decreased appetite for phosphorus. We found also that pregnant and lactating rats given free access to a large selection of minerals, vitamins, purified (or nearly purified) fats, proteins and carbohydrates, all in separate containers, make selections in accordance with their needs. They increased their intake of calcium, phosphorus, protein and fat.

There can be little doubt, then, that with his increased salt craving the 3½ year old boy with deficient adrenal cortical tissue made an effort to maintain a normal internal salt balance. Apparently he started as early as eleven months after birth. During the two and one half years previous to his entrance to the hospital he must have kept himself alive by eating large amounts of salt. In the hospital he was not given free access to salt but was given the regular ward diet, which contains the normal amount of salt and, as a result, died suddenly.

The basis for special cravings has not yet been established. We do not know whether the adrenalectomized rats eat large amounts of salt because the ingestion of salt makes them feel better or because their taste for salt has changed—in other words, that in their salt deficient state they become chemotrophically attracted to salt. In favor of the latter view is the observation that adrenalectomized rats have a greatly decreased

threshold for salt. They distinguish distilled water from 5% solution in a 1:33,000 concentration, while normal rats do not make this distinction until the salt solution reaches a concentration of 1:2,000.⁶ Such minimal amounts of salt as are received in drinking a few cubic centimeters of a 1:33,000 solution could not possibly have any physiologic effect. This boy also showed a positive reaction to salt when he first tasted it in pure form in very small quantities on the top of soda crackers. It is not readily conceivable that such a small amount of salt could have had any detectable effect on his deficiency condition.

SUMMARY

A boy aged 3½ years with deficient adrenal cortical tissue, manifesting various symptoms of adrenal insufficiency, had a marked craving for salt. On the basis of observations made on adrenalectomized rats, it would seem that this boy, by increasing his salt intake, kept himself alive for at least two and one half years.

A NEW TUBE FOR USE IN THE TREATMENT OF EMPYEMA BY OPEN DRAINAGE

LEON J. LEAHY, M.D., BUFFALO

It appears to be generally accepted that cases of empyema must be individualized and the proper treatment instituted to meet the conditions present. The chief factors influencing this are the age of the patient, the character of the exudate and the presence of complications. In most large series it is noted that the vast majority of cases require open drainage, such other methods as aspiration and closed drainage being reserved for the instances in which it is felt that the open method is either unsafe or not warranted. At times one of these procedures is used as a preliminary measure before establishing open drainage.

In instituting and maintaining open drainage I have encountered several difficulties which, although of a minor nature, could easily contribute to chronicity or recurrence if they were not recognized early or handled properly. The first of these has to do with the prevention of the tube from either slipping into the pleural cavity or coming out with the dressing. Sutures through the tube are satisfactory only until such time as they slough through the skin. A safety pin inserted through the tube and held to the chest wall with adhesive tape is an acceptable makeshift. However, the strips become readily loosened by the moisture from drainage and irrigations, thus allowing

Fig. 1.—Tube and flanges bent forward for introduction into the pleural cavity.

the tube to slip out of the pleural cavity unless care is exercised. As the inner end of the sinus closes very readily after the end of the tube has come out of the pleural cavity, reintroduction of the tube is often unsatisfactory. The next problem has to do with the inner end of the tube; it can easily be allowed to project into the pleural cavity for a distance of 1 or 2 inches, and with the use of modern gum rubber tubing it is difficult to recognize this fact even on the x-ray film without the injection of an opaque substance. I feel that if the end of the tube is not at the level of the parietal pleura the portion of the pleural cavity about the drainage tube is not kept emptied. This is in spite of secondary openings made in the sides of the tube, as these seem to become plugged with fibrin or granulations. There is the added factor of increased morbidity because the lung in reexpanding comes in contact with the end of the tube, and I feel that the speed of reexpansion

3. Loeb, R. F.: *Proc. Soc. Exper. Biol. & Med.* 30: 808 (March) 1933. Harrop, G. A.; Soffer, L. J.; Ellsworth, Read, and Trescher, J. H.: *J. Exper. Med.* 58: 17 (July) 1933. Rubin, M. L., and Krick, E. T.: *Proc. Soc. Exper. Biol. & Med.* 31: 228 (Nov.) 1933.
4. Richter, C. P.: *Am. J. Physiol.* 115: 155 (March) 1936.
5. Richter, C. P., and Eckert, J. F.: *Endocrinology* 21: 50 (Jan.) 1937. Richter, C. P., and Eckert, J. F.: *Am. J. M. Sc.* 108: 9 (July) 1939.

6. Richter, C. P.: *Endocrinology* 24: 367 (March) 1939. From the Department of Surgery, University of Buffalo School of Medicine. The instrument is made by the George P. Pilling & Son Company, Philadelphia.

is slowed up from this point onward and a small residual pocket is left which is not obliterated until the tube is entirely withdrawn from the pleural cavity. The possibility of pressure necrosis on the surface of the lung from contact with the tube with resultant bronchopleural fistula or bleeding is likewise present. Finally, to accomplish irrigation of the empyemic cavity it is necessary either to introduce a second tube or to irrigate through the large tube. The former method is rather inconvenient and the latter method often serves to wash large plugs of fibrin back into the pleural cavity.

To overcome the difficulties mentioned, I have designed a tube for open drainage which has been entirely satisfactory in my hands. This tube is of sufficient caliber to provide

Fig. 2.—A, cross section showing tube in position with relationship of the inner end to the parietal pleura. B, appearance of the outer end with pin in place and wound closed. C, cross section showing tube in position following reexpansion of the lung.

adequate drainage for even thick fibrin and has a small tube incorporated for secondary irrigations. There are two flexible rubber flanges on the inner end, which prevent the tube from slipping out of the pleural cavity. In addition they keep the point of drainage at the level of the parietal pleura, thereby allowing the lung to reexpand to the chest wall without striking the tube and also obviating the danger of pressure necrosis on the pulmonary surface. The safety pin is put through the tube at the skin level and in this manner the tube is made self retaining and consequently cannot slip into or out of the pleural cavity. No adhesive tape is necessary, and the only sutures used are interrupted sutures, employed to approximate the edges of the wound. Owing to the variation in thickness of the chest wall, depending on the site of operation and the build of individual, the safety pin has proved the most satisfactory handling of this problem. This tube is easily introduced, as the flanges are flexible and the gussets cut in the sides allow them to be bent forward. These also permit easy withdrawal following reexpansion of the lung. There is no necessity for removal of the tube until the empyemic cavity is obliterated.

SUMMARY

A new tube for open drainage in empyema is presented which has the following advantages:

1. It is easily introduced and withdrawn.
2. It is self retaining.
3. It can be reused many times.
4. It has adequate provision for secondary irrigations without the use of another tube.
5. The inner end of the tube is flush with the chest wall, therefore allowing more satisfactory drainage of the pleural cavity and complete reexpansion of the lung and obviating the danger of pressure necrosis.

40 West North Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

SCANLAN-MORRIS OXYGEN REGULATORS ACCEPTABLE

Distributor: The Scanlan-Morris Company, Madison, Wis.

Manufacturer: The Bastian-Blessing Company, Chicago.

Designed to meter the flow of oxygen, the Scanlan-Morris Oxygen Regulators are applicable to anesthesia apparatus, oxygen tents, nasal catheters and any similar oxygen therapy chambers. The numbers of the models distributed by Scanlan-Morris are A1473, A1474 and A1475, and these are designated by Bastian-Blessing as G-6121, G-6161 and T-6162 respectively.

The model A1473 is a single stage regulator provided in different sizes and with various types of flow-indicating and control units. The larger sizes provide greater durability and accuracy of control. The gas may enter the inlet of the regulator at varying pressures up to 2,000 pounds. The gas is released at the outlet by turning a screw until the gage connected to the expansion chamber of the regulator registers the desired flow. The valve on the outlet is so regulated by a spring and diaphragm that any desired volume of gas at a fixed pressure can be obtained. Vent holes are provided to release pressure in the event of the failure of the diaphragm. The regulator bonnets are also built with a shearing edge that cuts the diaphragm and allows the gas to escape before any dangerous excess pressure can build up.

The model A1474 is a double stage regulator equipped with a dial type, Bourdon tube, liter-flow indicating gage, which is calibrated in liters per minute from 0 to 15 against a fixed orifice of discharge. A simple discharge outlet permits the discharge only of the volume of gas indicated on the flow meter.

The model A1475 is also a double stage regulator but is equipped with a Thorpe tube flow indicator, consisting of a vertical tube of resinous plastic material highly resistant to fracture. A stainless steel flow ball indicates the relative volume of oxygen discharge against a calibrated plate, which is fixed to the reinforcing sleeve around the Thorpe tube. To facilitate the adjustment for various volumes of flow, the inlet of the Thorpe tube is provided with a restrictive orifice which acts as a choke. This device is also equipped with a spring valve by-pass, permitting a direct discharge of oxygen from the regulator to the outlet without passing through the flow indicator. This is to provide oxygen more rapidly in cases of emergency.

Both of the two-stage models are available with and without by-pass valves. In both models the variation in flow is accomplished directly by varying the pressure against restricting orifices. The discharge pressure beyond the orifices in all cases is nominally at atmospheric pressure.

When the gas pressure is regulated in two stages, the first stage pressure setting is fixed at the factory to deliver gas at a pressure of 150 pounds to the second stage. This setting allows an adjustable delivery range from 0 to 75 pounds from the outlet of the unit. By entirely releasing or removing the adjusting screw at the first stage, one reduces the flow to the second stage from 150 to 75 pounds. This permits a greater sensitivity to the new 0 to 55 pounds delivery range provided by the second stage adjustment. Positively connected seat and diaphragm assemblies are employed in a nozzle type first stage and a stem type second stage, in which neither stage depends on springs to shut off the gas. The claim is made that a positively constant delivery pressure is maintained as the cylinder pressure diminishes from 2,000 down to about 45 pounds, permitting the use of approximately 98 per cent of the contained gas in a cylinder without readjusting the flow rate.

Scanlan-Morris Oxygen
Regulators,
Model 1475.

A filtering device is incorporated in the inlet, consisting of two cylindric sections of monel mesh screen between which is an inert filtering compound. This is to eliminate destructive wear on the seat by preventing the entrance of finely divided particles of dirt. Located between the first and second stages is a spring-loaded safety relief valve, which is set to function at 300 pounds pressure to protect the inlet of the second stage against possible excess pressure coming from the first stage in the event that the first stage did not close off at 150 pounds pressure. The firm states further that, if anything should happen to the safety device, the first stage is so built that it can withstand 2,000 pounds pressure. In order to substantiate the efficiency of the regulator in maintaining a constant delivery pressure with a lowering of the cylinder pressure, the firm submitted comparative curves for this regulator and six other competitive regulators. One group of tests was made with the delivery pressure set at 5 pounds and a second group with the delivery set at approximately $1\frac{3}{4}$ pounds (the weight of a 50 inch column of water). In all cases the regulator under consideration gave a straight-line curve down to about the last 50 pounds pressure in the cylinder.

The regulators were submitted for a Council investigation, from which it was determined that they are well constructed and satisfactory. The flow meter is sufficiently accurate for clinical use at the indicated liter levels. It appeared to hold a given indicated rate of flow over long periods of time.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Scanlan-Morris Oxygen Regulators for inclusion on the Council's list of accepted devices.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

SULFATHIAZOLE AND SULFAMETHYLTHIAZOLE

FOLLOWING THE INTRODUCTION OF SULFAPYRIDINE IT WAS TO BE EXPECTED THAT RESEARCH LABORATORIES WOULD PREPARE OTHER DERIVATIVES OF SULFANILAMIDE FOR PURPOSES OF INVESTIGATION. RECENTLY THERE HAVE BEEN REPORTS THAT TWO DERIVATIVES IN PARTICULAR, SULFATHIAZOLE (2(PARA-AMINO-BENZENE-SULFONAMIDO) THIAZOLE) AND SULFAMETHYLTHIAZOLE (2(PARA-AMINO-BENZENE-SULFONAMIDO) 4-METHYLTHIAZOLE) GIVE SOME PROMISE OF THERAPEUTIC MERIT. THE COUNCIL HAS NOT GIVEN CONSIDERATION TO THE ACCEPTABILITY OF THE NAMES SULFATHIAZOLE AND SULFAMETHYLTHIAZOLE. THE MEDICAL PROFESSION HAS SUCH INTEREST IN SULFANILAMIDE AND ITS DERIVATIVES THAT DR. PERRIN H. LONG WAS ASKED IF HE WOULD PREPARE A PRELIMINARY REPORT ON THESE TWO SUBSTANCES. THE COUNCIL CONCURS WITH HIS CONCLUSIONS AND EXPRESSES ITS APPRECIATION OF DR. LONG'S AID.

THE TWO PREPARATIONS HAVE NOT BEEN LICENSED BY THE FOOD AND DRUG ADMINISTRATION FOR SALE IN INTERSTATE COMMERCE (AS NEW DRUGS). THIS GIVES OPPORTUNITY FOR THE MEDICAL PROFESSION TO BE INFORMED ABOUT THE DRUGS BEFORE THEY ARE EXPLOITED. NO FIRM HAS SUBMITTED THESE DRUGS FOR CONSIDERATION BY THE COUNCIL. THE COUNCIL ADOPTED DR. LONG'S REPORT AND HAS AUTHORIZED ITS PUBLICATION AS A PRELIMINARY REPORT OF THE COUNCIL.

PAUL NICHOLAS LEECH, Secretary.

THIAZOLE DERIVATIVES OF SULFANILAMIDE

SULFATHIAZOLE AND SULFAMETHYLTHIAZOLE

PERRIN H. LONG, M.D.

BALTIMORE

Recently, Fosbinder and Walter¹ have described the preparation of certain sulfanilamide derivatives of heterocyclic amines. Among these compounds were described sulfanilamide derivatives of the thiazole series, namely 2 - para-nitro - benzenesulfonamido - 4-methylthiazole, 2-N⁴-acetylsulfanilamido-4-methylthiazole, 2-N⁴-acetylsulfanilamidothiazole, 2-sulfanilamido-4-methylthiazole and 2-sulfanilamidothiazole. Similar

compounds have been synthesized by Lott and Bergeim.² Two of these compounds, sulfathiazole (2(para-amino-benzene-sulfonamido) thiazole) and sulfamethylthiazole (2(para-amino-benzene-sulfonamido) 4-methylthiazole) have been distributed for experimental use and clinical investigation. The names have not yet been considered by the Council on Pharmacy and Chemistry.

It has been reported³ that the acute toxicity of sulfathiazole (when administered as the sodium salt by the parenteral route) is definitely less than that of the corresponding sodium salt of sulfapyridine when administered by the same route. The experience with this compound in our division confirms this observation, and we have noted that the sodium salt of the methyl and phenyl derivatives of sulfathiazole are about as acutely toxic for mice as is the sodium salt of sulfapyridine. Hence, from this point of view, it can be definitely said that, in acute toxicity experiments in mice, sulfathiazole is less toxic than its methyl derivative, phenyl derivative and sulfapyridine. Van Dyke and his co-workers⁴ found that the chronic toxicity of sulfathiazole in mice was definitely greater than that of sulfapyridine when these compounds were fed in the diets in concentrations of 2 per cent. Sulfapyridine, however, appeared to be more toxic for growing rats than was sulfathiazole and in monkeys large doses of sulfapyridine produced unilateral or bilateral hydro-ureter and hydronephrosis together with hematuria and albuminuria in six of seven monkeys, while but one in seven monkeys given large doses of sulfathiazole showed like changes. Rake and his associates⁵ noted microscopic lesions in the kidneys, livers and spleens of mice chronically poisoned with sulfathiazole. Similar doses of sulfapyridine produced only hepatic lesions in mice. In rats and monkeys, little evidence of injury was found after intensive sulfathiazole therapy. It would seem from these studies that the chronic toxicity of sulfathiazole for mice is definitely greater than is that of sulfapyridine, while in rats and monkeys sulfapyridine is the more toxic compound. Further studies⁶ revealed that in mice sulfathiazole disappears from the blood more rapidly than does sulfapyridine, and in rats and monkeys it was noted that sulfathiazole was excreted more rapidly than was sulfapyridine and that the proportion of conjugated sulfathiazole excreted in the urine of these animals was much less than was the case with sulfapyridine. We have noted also that sulfathiazole disappears rapidly from the blood of mice.

The therapeutic effect of these compounds on experimental pneumococcic, meningococcic, hemolytic streptococcic and lymphogranuloma venereum infections in mice has been tested by McKee and her associates.⁷ It has been shown, as a result of these studies that, when sulfathiazole is administered as 1 per cent of the diet, its therapeutic effects are of the same order of those of sulfapyridine in the control of experimental pneumococcic infections in mice. If 0.5 per cent of the drugs were used in the diets, sulfapyridine was consistently slightly more effective than sulfathiazole. The results obtained in experimental streptococcic, meningococcic and lymphogranuloma venereum infections with sulfathiazole therapy were of the same order

as were observed when sulfapyridine was used, but, as small numbers of mice were used and practically all of those treated survived, no conclusions as to the effect of the drug can be drawn. Cooper and his co-workers⁶ have reported that sulfathiazole and sulfamethylthiazole are less effective than sulfapyridine in the control of experimental type II pneumococcal and streptococcal infections in mice. Here again too few mice were used to make the reported observations statistically significant. Our own experiments in experimental hemolytic streptococcal and pneumococcal infections in mice lead me to believe that sulfathiazole is somewhat less effective than sulfapyridine as a therapeutic agent when administered in suspension by the peroral route. However, when the drug is administered in a 1 per cent concentration in the diet of the infected mice it seems to be equal to sulfapyridine in its therapeutic efficiency in these infections. In experimental staphylococcal infections in mice sulfathiazole has proved somewhat superior to sulfapyridine. The differences noted in the therapeutic result obtained when the two drugs are administered in suspension by the oral route (as compared with giving it in the food) in experimental infections in mice may be accounted for by the more rapid disappearance of sulfathiazole from the blood of the treated mice.

Recently we have carried out studies on the absorption, distribution and excretion of sulfathiazole in man. These studies indicate that the drug is more readily absorbed from the gastrointestinal tract than is sulfapyridine and that in this respect it approaches sulfanilamide. In the blood the ratio of the free and conjugated fractions of the drug also resembles that of sulfanilamide, differing again in this respect from sulfapyridine. Sulfathiazole is excreted much more rapidly than is sulfapyridine, if renal function is normal. In the urine much less sulfathiazole exists in the acetylated or conjugated form than is the case with sulfapyridine. Sulfathiazole seems to be distributed in exudates and transudates in about the same ratio as has been noted previously for sulfanilamide.

It is too early to pronounce on the comparative clinical therapeutic effects of sulfathiazole and sulfapyridine. However, our experience to date leads us to believe that it is about as effective as sulfapyridine in pneumococcal pneumonia in human beings and at least as effective as sulfapyridine, if not more so, in staphylococcal infections in man.

We have noted in the course of clinical experiments with sulfathiazole that there seemed to be definitely less nausea and vomiting produced by this drug than we should have expected from sulfapyridine. Drug fever and drug rashes have been quite common and, in addition, we have noted three instances of a rather marked congestion of the conjunctivas and scleras in association with an erythematous papular and nodular eruption which was generalized over the extremities and face. The eruption resembled that of erythema nodosum. In one case an injection of the sclera of one eye alone, without an eruption, was observed. These ocular manifestations of sulfathiazole toxicity may be preceded by burning and smarting of the eyes. In at least one case the eruption and conjunctivas seemed to be associated with photosensitization.

Sulfathiazole does not seem to cause a fall in the carbon dioxide combining power of the plasma. Mild

hematuria has been noted in several cases. In one case anuria of forty-eight hours' duration with azotemia but without hypertension or changes in the retina developed shortly after treatment with sulfathiazole had been discontinued. In view of the toxic reactions just described, it is to be expected that sulfathiazole will produce essentially the same clinical toxic manifestations previously described as occurring in the course of treatment with sulfanilamide or sulfapyridine.

Not enough is known as yet to set up standards of dosage. For adult patients ill with pneumococcal pneumonia it has been my custom to prescribe initial doses of 4 Gm. of sulfathiazole, this to be followed at four hour intervals by doses of 1 Gm. of the drug. Using this schedule we have noticed that after the first twenty-four hours of medication the concentrations of sulfathiazole in the blood are frequently much lower than would be expected if sulfapyridine had been administered, and in certain instances it has been difficult to maintain adequate concentrations of the drug in the blood of patients, despite increases in the amount of drug prescribed. This we attribute to the rapid absorption and excretion of the drug. In several cases a relapse of the pneumonia has been noted in association with these low concentrations of sulfathiazole.

There is little available published data concerning the experimental use of sulfamethylthiazole. Herrell and Brown⁷ have stated "It appears that sulfamethylthiazole is a rather efficient drug in infections caused by pneumococcal and especially staphylococcal organisms."

The evaluation of these new chemotherapeutic compounds will necessitate extensive experimental and clinical investigations in order to determine their efficiency in the control of infections and their clinical toxic manifestations. Until the time when such data are in hand, it is to be hoped that enthusiasms do not outrun common sense.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156).

Beech-Nut Packing Company, Canajoharie, N. Y.

BEECH-NUT BRAND CHOPPED LIVER AND BEEF SOUP WITH VEGETABLES, BARLEY AND RICE, composition reported by manufacturer to be the same as that of Beech-Nut Brand Strained Liver and Beef Soup with Vegetables, Barley and Rice.

Libby, McNeill & Libby, Chicago.

LIBBY'S BRAND HOMOGENIZED PEAS.

Analysis (submitted by manufacturer).—Moisture 85.4%, total solids 14.6%, ash 1.1%, sodium chloride 0.4%, fat (ether extract) 0.1%, protein (N \times 6.25) 3.5%, crude fiber 1.8%, carbohydrate other than crude fiber (by difference) 8.1%, calcium (Ca) 11.0 mg. per 100 Gm., phosphorus (P) 32.8 mg. per 100 Gm., iron (Fe) 2.3 mg. per 100 Gm., copper (Cu) 0.229 mg. per 100 Gm.

Calories.—0.49 per gram; 13.9 per ounce.

Vitamins.—Protocols of biologic assay (1939) show that the product contains 4.0 U. S. P. units of vitamin A per gram, 114 per ounce; 0.34 international units of vitamin B₁ per gram, 9.7 per ounce; 0.20 Sherman-Bourquin units of vitamin G (riboflavin) per gram, 5.7 per ounce; and according to a report of chemical titration (1939) 0.51 international unit of vitamin C per gram, 16.8 per ounce.

SATURDAY, MARCH 9, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

DESICCATED BILE

The proper absorption of vitamin K, which takes place only in the presence of an adequate amount of bile in the intestine, is apparently a major factor in the maintenance of a normal level of prothrombin in the blood. Of especial interest in this connection is the suggestion that the clotting deficiency in obstructive jaundice is directly related to improper absorption of vitamin K as the result of lack of necessary biliary constituents in the intestine.¹ This view is in accord with the earlier observation that the hemorrhagic tendency in jaundice may be caused by a diminution of prothrombin.² The therapeutic use of desiccated bile in the treatment of obstructive jaundice has been³ suggested. When the administration of bile to a patient is indicated, the advantages of dried bile over fresh

bile are apparent, since the latter has a tendency to deteriorate and is unpleasant to administer. If desiccated bile is used as a substitute for fresh bile, however, it is important to know whether or not the drying process in any way affects the chemical and physical properties of the product.

A recent report by Johnston and his associates⁴ offers the comparative composition of desiccated and normal hog gallbladder bile. The composition of dried bile, prepared from fresh hog bile by evaporating it to dryness under a high vacuum and at a low temperature, is compared to the chemical makeup of the same bile before dessication. The dry powder prepared from bile dissolves readily in water to yield a solution closely resembling the original bile. Except for some loss of carbon dioxide, the inorganic constituents are not appreciably altered by the process of desiccation. Similarly, the procedure has little effect on the cholesterol, bilirubin, fatty acid, mucin and bile acid content of bile. Moreover, there is little change in the surface tension and viscosity of an aqueous solution of desiccated bile as compared with the physical properties of the original bile. The increase in the free choline, which is accompanied by a decrease in the amount of phospholipid, in the desiccated bile would not have a harmful effect, according to the Detroit investigators.

In general, the data obtained as a result of numerous analyses carried out on bile before and after drying indicate that it is possible to prepare desiccated bile by a mild treatment involving concentration in vacuo at a low temperature without significantly altering its chemical composition. A solution properly prepared from desiccated bile does not differ appreciably from whole bile with respect to its chemical and physical properties.

NATIONAL CONFERENCE ON MEDICAL NOMENCLATURE

On March 1 representatives of specialist societies, hospital organizations, government services and other interested groups met at the headquarters of the American Medical Association in Chicago as the National Conference on Medical Nomenclature. Many problems of classifying disease were considered, both in the form of papers and reports and in discussions. The formal classification of disease involves educational factors, questions of facilitating clinical research, the organization of hospital record libraries, comparative morbidity statistics and morbidity reports and the relation of morbidity to the International List of Causes of Death.

At the conference it was brought out by several of the speakers that eponyms are in general inadvisable as labels for disease. There is, perhaps, a trend toward the use of English rather than Latin terms in classifying disease, but it is, of course, impossible to separate all terms from their Latin or Greek derivatives. The confusion of terms in some branches of medicine, in

1. Dam, H., and Glavind, J.: *Acta med. Scandinav.* 96: 108, 1938.
Stewart, J. D.: *Ann. Surg.* 109: 588 (April) 1939.
2. Quick, A. J.; Stanley-Brown, Margaret, and Bancroft, F. W.: *Am. J. M. Sc.* 190: 501 (Oct.) 1935.
3. Johnston, C. G.: *Surgery* 3: 875 (June) 1938.

4. Irvin, J. L.; Merker, Harvey; Anderson, C. E., and Johnston, C. G.: *J. Biol. Chem.* 131: 439 (Dec.) 1939.

particular, was emphasized and the inevitable corollary that preferred terms should be chosen, even at the risk of occasional arbitrary decisions. It was also apparent that advance in some fields of medicine necessitates a reexamination of the entire subject of the classification of diseases in those fields.

Several papers and discussions dealt particularly with the methods which can be used in adapting the Standard Classified Nomenclature of Disease to clinical research and to the preparation of reports on the incidence of disease, from single hospitals or groups of hospitals, by the use of punch cards and tabulating methods. The demonstration of the uses to which such a classification can be put emphasizes the deficiencies heretofore existent in most summarizations of morbidity statistics. Indeed, what has been already accomplished may be considered to point the way toward more accurate and more extensive use of tabulating methods in the morbidity field.

The conference agreed unanimously that a similar conference should meet again in five years and that the Standard Classified Nomenclature of Disease be revised at periods of approximately five years. In the interim, it was suggested that an editorial advisory board be appointed to concern itself with problems which may require more constant supervision than can be attained by the periodic meetings of the National Conference itself. The conference approved the preparation of a standard nomenclature of operations. A complete summarized report of the conference will be published in forthcoming issues of *THE JOURNAL*.

THIAZOLE DERIVATIVES OF SULFANILAMIDE

Since the introduction of sulfanilamide into American therapeutics early in 1937 the Council on Pharmacy and Chemistry has followed new developments carefully. Both *THE JOURNAL* and the Council on Pharmacy and Chemistry have commented repeatedly on the necessity of careful administration of sulfanilamide and its compounds. The tremendous potentialities of the particular chemical grouping represented in the sulfanilamide compounds have warranted the belief that many new paths of therapeutic usefulness would be opened. Progress has been so rapid that the Council has been obliged to issue four succeeding revisions of its statement of actions and uses for the description of the drug in New and Nonofficial Remedies.¹

The introduction of sulfanilamide, as was to be expected, was soon followed by the presentation of a derivative representing a combination of pyridine and sulfanilamide, which received the nonproprietary term sulfapyridine. The Council on Pharmacy and Chemistry has also published recently a revised statement of the actions and uses of sulfapyridine,² necessitated by the additional knowledge beyond that obtainable in May 1939, when the product was accepted.

Now come reports of two more derivatives of sulfanilamide—sulfathiazole and sulfamethylthiazole. Elsewhere in this issue appears a preliminary report of the Council, prepared by Dr. Perrin H. Long,³ on these substances. All of these sulfanilamide derivatives are quite similar in their basic character, as is illustrated by the following graphic formulas:

It is too early to state definitely just what advantages, if any, these derivatives may have over sulfanilamide and sulfapyridine. One group of workers (Herrell and Brown) have stated that sulfamethylthiazole has been found efficient in the treatment of some infections caused by staphylococcus organisms. Further investigation of the effectiveness of the compound in diseases caused by staphylococci is decidedly in order, for if the product is found to be of value in these diseases it certainly will have advantages over sulfanilamide. Again it is fortunate that the product has not been placed on the open market before physicians are given an opportunity to know more about it. In this way, unwise use will be minimized and its true merit can be properly evaluated in those laboratories which have competent facilities for such investigation. As Dr. Long concludes in the preliminary report: "The evaluation of these new chemotherapeutic compounds will necessitate extensive experimental and clinical investigations in order to determine their efficiency in the control of infections and their clinical toxic manifestations. Until the time when such data are in hand, it is to be hoped that enthusiasms do not outrun common sense."

Current Comment

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the third time at the opening general meeting at the annual session of the Association in New York on June 11. This medal was awarded in 1938 to Dr. Rudolph Matas, distinguished surgeon of New Orleans, and last year to Dr. James B. Herrick of Chicago. By the system of selection this award has come to be recognized as one of the most distinguished honors within the gift of the Association. The method of selection of the recipient of the Distinguished Service Medal is specifically defined in the By-Laws of the Association. Any Fel-

1. Sulfanilamide, *J. A. M. A.* 114: 326 (Jan. 27) 1940.

2. Sulfapyridine, *J. A. M. A.* 114: 327 (Jan. 27) 1940.

3. Long, P. H.: Thiazole Derivatives of Sulfanilamide, this issue, p. 870.

low of the Association may submit nominations, which should be sent, together with a record of the scientific services of the nominees, to the chairman of the Committee on Distinguished Service Awards or to the Secretary of the Association. Dr. Grant C. Madill, 214 King Street, Ogdensburg, N. Y., is chairman of the Committee on Distinguished Service Awards. Of all nominations received by the committee, five are submitted to the Board of Trustees of the Association, from which the Board selects three to be submitted to the House of Delegates at its first meeting. Immediately on submission of the nominations by the Board of Trustees, the House of Delegates by official vote selects the recipient of the honor, to whom the Distinguished Service Medal is presented on the evening of the following day. Obviously, an extended list of distinguished physicians nominated for this award will enable the Committee on Awards, the Board of Trustees and the House of Delegates, all of whom participate in the selection, to determine for 1940 a recipient of distinction, whose nomination again will reflect favorably not only on himself but also on the Association.

UNITED STATES COURT OF APPEALS REVERSES DECISION OF LOWER COURT

The United States Court of Appeals on March 4 reversed a district court decision by Justice Proctor that medicine was a "learned profession" and therefore not within the scope of the Sherman antitrust act. As part of its decision, the Court of Appeals said "The fact that defendants are physicians and medical organizations is of no significance." At the heart of the litigation is the question whether the law against restraint of trade applies to the medical profession. The court said "We think enough has been said to demonstrate that the common law governing restraint of trade has not been confined, as defendants insist, to the field of commercial activity, ordinarily defined as 'trade,' but embraces as well the field of the medical profession." Again the court said: "It cannot be admitted that the medical profession may through its great medical societies, either by rule or disciplinary proceedings, legally effectuate restraints as far reaching as those now charged." In addition the Court of Appeals held that, while the charge against the American Medical Association may be wholly unwarranted, "For present purposes we must take the charge as though its verity were established; and, in that light, it seems to us clear that the offense is within the condemnation of the statute." The court also said "It certainly cannot be doubted, that Congress intended to exert its full power in the public interest, to set free from unreasonable obstruction the exercise of those rights and privileges which are a part of our constitutional inheritance, and these include immunity from compulsory work at the will of another, the right

to choose an occupation, the right to engage in any lawful calling for which one has the requisite capacity, skill, material or capital, and thereafter free enjoyment of the fruits of one's labors." And, it stated, "Congress undoubtedly legislated on the common law principle that every person has individually, and that the public has collectively, a right to require the course of all legitimate occupations in the District of Columbia to be free from unreasonable obstruction, and likewise in recognition of the fact that all trades, businesses and professions which prevent idleness and exercise men in labor and employment for the benefit of themselves and their families and for the increase of their substance are desirable in the public good and any undue restraint upon them is wrong and is immediate and unreasonable and, therefore, within the purview of the Sherman act." Further, the court said, "we are mindful of a generally known fact that under these rules and standards [of the medical profession] there has developed an *esprit de corps* largely as a result of which the members of the profession contribute a considerable portion of their time to the relief of the unfortunate and the destitute. All of which may well be acknowledged to their credit. Notwithstanding these important considerations, it cannot be admitted that the medical profession may, through its great medical societies, either by rule or disciplinary proceedings, legally effectuate restraints as far reaching as those now charged." Although the attorneys for the American Medical Association have not yet reached a decision as to the next step to be followed, it seems reasonable to believe that they will now go to the United States Supreme Court with a request for a definite decision as to whether or not the practice of medicine comes within the purview of the Sherman antitrust law.

COURT OF APPEALS RULES AGAINST BRINKLEY

Last week the United States Fifth Circuit Court of Appeals at New Orleans upheld a federal district court decision in the libel suit brought by John R. Brinkley against the editor of *Hygeia*. The statement of the court in making this decision was as follows:

We are spared the necessity of discussing the assignments of error in this decision and of reviewing the evidence. It is sufficient to say that the evidence of the plaintiff, placed on the stand by the defendant, tends to show the truth of the statements of fact complained of, and we find no substantial evidence tending to show the defendant was actuated by malice or that plaintiff suffered any actual damage compensable in money.

In the presentation of its case before the federal district court the American Medical Association revealed a long trail of dubious medical activities on the part of Dr. John R. Brinkley for which there was no refutation. In the meantime he continues to broadcast from his station across the Rio Grande, and the United States Post Office continues to permit him the use of the United States mails.

During 1939 the legislatures of all the states, except Kentucky, Louisiana, Mississippi and Virginia, met in regular session, and special sessions were also held in five of them. More than 63,000 proposals were considered, of which not less than 4,000 were of definite medical interest. This survey, however, must be limited to reporting as briefly as possible what are deemed to be the more significant of those proposals—significant from the standpoint of public health and the medical profession. To expedite perusal for those more interested in ascertaining what the legislatures have perpetrated in the name of legislation than what could have been or may in the future be, enactments are printed in larger (10 point) type, while proposals failing of enactment and footnotes are printed in the usual type of the survey (8 point and 6 point).

I. STATE MEDICINE: COMPULSORY AND VOLUNTARY MEDICAL, DENTAL AND HOSPITAL SERVICE PLANS

COMPULSORY HEALTH INSURANCE.—Bills similar to, if not identical with, "The Social Security Bill for Health Insurance," prepared by the American Association for Social Security, failed of enactment in California,¹ Connecticut,² Massachusetts,³ New York,⁴ Pennsylvania,⁵ Rhode Island⁶ and Wisconsin.⁷ These bills proposed a system of compulsory and voluntary sickness insurance, the benefits of which were to consist of cash in all forms of medical, dental and hospital service. In most of them, persons employed at "other than manual labor" and receiving wages in excess of \$60 a week, farm laborers and per-

sous employed by an employer having less than three employees in personal or domestic services were to be excluded from the compulsory insurance of the bill but were to be entitled to participate in the voluntary insurance. All other employees were embraced in the compulsory feature of these bills.

The life of the committee authorized by New York Laws, 1938, c. 682, to investigate the health requirements of the people and to recommend such health insurance proposals with respect to state medicine as it deems advisable was extended to March 15, 1940, by a New York law.⁸

Bills were killed in Connecticut⁹ and Ohio¹⁰ to create commissions to study the subject of health insurance, with a view to establishing systems of health insurance for the states and to report to the legislature recommendations for appropriate legislation.

VOLUNTARY MEDICAL SERVICE PLANS.—Laws were enacted in Connecticut,¹¹ Michigan,¹² New York,¹³ Pennsylvania¹⁴ and Vermont¹⁵ permitting nonprofit corporations which are authorized by a designated state agency to do so to operate on a prepayment basis nonprofit medical service plans whereby stated medical services and care may be rendered at the expense of the corporations to subscribers to such plans and their dependents. Generally speaking, these plans contemplate that the subscriber shall have available the services of a physician of his own choice and that the corporation itself will pay the bills incurred to the phy-

5. Pa. H. 671.
6. R. I. H. 809.
7. Wis. A. 897.

A new Georgia law⁵⁴ authorizes counties to levy a 1 mill tax to provide medical care and hospitalization for indigent sick residents.

A new Texas law⁵⁵ authorizes each county to levy a tax not to exceed 10c on the hundred dollar valuation on taxable property to buy necessary vaccines and to pay for the necessary medical services required for the immunization of school children and indigents from communicable diseases and to pay as much as one half for medical treatment and hospitalization of people not paupers.

Another Texas bill, which failed of enactment,⁵⁶ proposed to create a state department of hospitalization and medical care to provide for the hospitalization and treatment of the indigent sick and indigent expectant mothers.

An unsuccessful attempt was made in New Mexico⁵⁷ to authorize the board of county commissioners of each county to employ a county health physician and a county health nurse. Two Oklahoma bills,⁵⁸ which were killed, proposed to authorize the state commissioner of health to appoint one regularly licensed physician for each county in the state to give medical treatment free of charge to such persons as would make affidavit that they were unable to pay for treatment.

Unsuccessful attempts were made in Connecticut⁵⁹ and Illinois⁶⁰ to provide for the rendering of medical services at state expense to recipients of old age assistance. An unsuccessful Washington bill⁶¹ provided somewhat similar services with respect to recipients of blind assistance.

Laws were enacted in Connecticut,⁶² Illinois⁶³ Indiana⁶⁴ and New Jersey,⁶⁵ appropriating stated sums to the state board or department of health for the purchase and free distribution of pneumococcus serum for the treatment of persons afflicted with pneumonia and financially unable to purchase the serum. No specific appropriation was made in the Connecticut law, while the appropriation in Illinois was \$75,000, \$95,000 in Indiana and \$25,000 in New Jersey. The Indiana laws authorize the distribution also of diphtheria toxoid, smallpox virus and typhoid bacterins.

A new Florida law⁶⁶ appropriates \$10,000 to the state board of health with which it is to purchase and distribute insulin to persons needing it and financially unable to purchase it.

A somewhat similar bill was killed in Wisconsin.⁶⁷

A new Connecticut law⁶⁸ authorizes the state department of health to furnish such treatment to indigent typhoid or paratyphoid fever germ carriers as may be necessary to relieve them of the carrier state.

An unsuccessful Pennsylvania bill⁶⁹ proposed to authorize the department of welfare to supply hearing aids or devices to persons who are deaf or hard of hearing and who are financially unable to purchase them.

Two New York bills, which were killed,⁷⁰ proposed to require local boards of health and local health officers to provide to persons infected with poliomyelitis suitable surgical, medical or therapeutic treatment or hospital care and necessary appliances and devices provided the person so infected was not able financially to provide for himself. Two other unsuccessful New

York bills⁷¹ proposed to impose on counties or other political subdivisions the duty of supplying such "physical repair" to physically handicapped unemployed adult persons and to require the state to reimburse the local political subdivisions 75 per cent of the total expended by them for such purpose. Two other New York bills, which likewise failed of enactment⁷² proposed to create a temporary commission to survey the existence and prevalence of hay fever in the state, to devise ways and means for its prevention and elimination and to recommend methods for the treatment, relief and cure of persons suffering from hay fever.

Legislation relating to cancer control and the extent of aid rendered at public expense to afflicted persons will be subsequently discussed in this survey at p. 879.

II. LEGISLATION AIMED AT THE CONTROL OF VENEREAL DISEASE, DIPHTHERIA, CANCER AND OTHER DISEASES

PREMARITAL EXAMINATIONS.—Laws to require as a condition precedent to the issuance of a marriage license that each party to the proposed marriage present a certificate of a licensed physician that the party has been given such examination, including a standard serologic test, as may be necessary for the discovery of syphilis, made on a day specified in the statement, which shall be not more than thirty days prior to the day on which the license is applied for, and that in the opinion of the physician the party named is not infected with syphilis or, if so affected, is not in a stage of that disease whereby it is communicable, were enacted in California,⁷³ Colorado,⁷⁴ Indiana,⁷⁵ North Carolina,⁷⁶ North Dakota,⁷⁷ Pennsylvania,⁷⁸ South Dakota,⁷⁹ Tennessee⁸⁰ and West Virginia.⁸¹ In addition, the North Carolina and Tennessee laws require a similar statement with respect to all venereal diseases.

Proposals to condition the issuance of a license to marry on the presentation by both parties to the proposed marriage of a physician's certificate as to freedom from an infectious stage of a stated venereal disease were rejected in sixteen other states.⁸²

Existing laws requiring premarital examinations were amended in Illinois,⁸³ Michigan⁸⁴ and New York.⁸⁵ The principal change effected by the new Illinois law is to provide that the laboratory tests for venereal diseases prescribed in the act must be tests approved by the state department of public health and must be made by laboratories of that department or by such other laboratories as the department approves. The new Michigan law raises to thirty days from fifteen days the period prior to the issuance of a license to marry during which the applicants must have been examined for the presence of the stated venereal diseases. The law also requires freedom on the part of

85. New York, Laws, 1939, c. 110.

the applicants from an infectious stage of syphilis, gonorrhea or chancroid, while the prior law required freedom from all venereal diseases. Laboratories which can make the indicated tests must be approved by the state commissioner of health. The test required in the new law for syphilis is "a serological test approved by the commissioner." The prior law required a Kahn test. The new New York law effects several minor changes in the prior law. Possibly the most important change effected is to provide that the examination conducted by the certifying physician must be made not earlier than thirty days prior to the date on which the license is applied for. The prior law contained a twenty day period.

Bills to amend existing premarital examination laws were killed in Oregon⁸⁶ and Wisconsin.⁸⁷ Both of these bills proposed certain state facilities to render the required laboratory examinations free of cost.

BLOOD TESTS OF PREGNANT WOMEN.—Laws to require a licensed physician or other person engaged in the antepartum care of a pregnant woman, or attending such a woman at the time of delivery, to obtain a specimen of her blood and to submit the specimen to an approved laboratory for a standard laboratory test for syphilis were enacted in California,⁸⁸ Colorado,⁸⁹ Delaware,⁹⁰ Illinois,⁹¹ Indiana,⁹² Iowa,⁹³ Maine,⁹⁴ Massachusetts,⁹⁵ Michigan,⁹⁶ North Carolina,⁹⁷ Oklahoma,⁹⁸ Pennsylvania,⁹⁹ South Dakota¹⁰⁰ and Washington.¹⁰¹

Similar bills were killed in six other states.¹⁰²

REPORTING OF VENEREAL DISEASE.—A new Alabama law¹⁰³ requires a physician diagnosing or treating a case of syphilis, gonorrhea, chancroid, venereal lymphogranuloma or granuloma venereum to report the facts immediately to the county health officer. The law requires a similar report from the superintendent or manager of a hospital, dispensary or penal or other institution in which there is a case of venereal disease.

A similar bill failed of enactment in New Jersey.¹⁰⁴

COMPULSORY TREATMENT OF VENEREAL DISEASE.—A new Alabama law¹⁰⁵ authorizes the county health officer to require all persons infected with a venereal disease to undergo treatment by a licensed physician and if such persons are unable to pay for such treatment the health officer may require them to submit to treatment at public expense. The law also authorizes the county health officer to isolate or quarantine persons infected with venereal disease and to commit to jail for treatment persons refusing to take or continue treatments as provided in the act.

FREE TREATMENT FOR INFECTED INDIGENTS.—A new Florida law¹⁰⁶ authorizes counties of from 53,000 to 57,000 population to provide medical treatment at county expense to all indigent residents suffering from venereal disease.

STATE FACILITIES FOR THE DIAGNOSIS OF VENEREAL DISEASE.—A new Oregon law¹⁰⁷ amends the prior law directing the state board of health to provide free of charge facilities for the necessary laboratory examinations for the diagnosis of venereal disease and to provide the necessary materials for the proper treatment of those diseases to persons whom the attending physician certifies are unable to pay therefor by requiring as a condition precedent to the rendition of the services and the supplying of the materials noted to the attending physician that the attending physician certify that he will make no charge to the patient for the treatment of the diseases for which the test is made.

DISTRIBUTION OF ANTISYPHILITIC DRUGS.—Bills were killed in Florida¹⁰⁸ and Utah¹⁰⁹ to provide for the distribution at state expense of stated antisyphilitic drugs to persons afflicted with syphilis who are financially unable to purchase them.

BLOOD TESTS OF PHYSICIANS, DENTISTS AND NURSES.—A bill was killed in Indiana¹¹⁰ which proposed to require every physician, dentist and nurse at least once every twenty-four months to cause to be submitted to an approved laboratory for a standard serologic test for syphilis a sample of his blood. If any such test should show that a physician, dentist or nurse was infected with syphilis the license of such person should be automatically suspended and remain suspended so long as the disease was in a stage whereby it was communicable.

SPECIFIC APPROPRIATIONS FOR THE ERADICATION OF VENEREAL DISEASE.—A new Colorado law¹¹¹ appropriates \$12,000 to the state board of health for the period ending June 30, 1941, to be used for "venereal disease control work."

A bill was killed in Texas¹¹² which proposed to appropriate \$150,000 to the state department of health to assist in the eradication of venereal disease in the state.

PHYSICAL EXAMINATION OF FOOD HANDLERS OR DOMESTIC SERVANTS.—A new Texas law¹¹³ prohibits the employment in any public eating or sleeping place or place where food, drink or candy is prepared, stored, packed or served of any person with an infectious or contagious disease. Any person so employed must present every six months a physician's certificate that he has examined the employee and has found him free from all infectious or contagious diseases.

Similar bills were killed in five states.¹¹⁴

The Governor of New York vetoed a bill¹¹⁵ proposing to prohibit a person with a communicable or contagious disease from working or being permitted to work in a factory wherein a food product is manufactured and to require any employee of such a factory when required by a medical inspector of the labor department to submit to a physical examination.

A bill was killed in New York¹¹⁶ to prohibit the employment as a domestic servant of any person who does not possess a physician's certificate as to freedom from syphilis and to require such servants to submit to an examination to determine that fact annually.

115. N. Y. A. 1303.

116. N. Y. A. 2242.

IMMUNIZATION TO DIPHTHERIA.—A law was enacted in North Carolina¹¹⁷ requiring the parents or guardian of any child in the state to have administered to the child between the ages of 6 and 12 months an immunizing dose of a prophylactic diphtheria agent approved by the United States Public Health Service. A similar duty rests on parents and guardians of children between 1 and 5 years of age who have not been immunized previously against diphtheria. If the parents or guardians are financially unable to pay a physician of their own choice to perform the required immunization, the appropriate county health officer is to administer such treatment free of charge.

A new New Jersey law¹¹⁸ authorizes any board of education to condition school attendance on proof of immunity to diphtheria. Such board may provide free of cost materials and services for the required immunization.

CANCER.—Laws aimed to aid in the eradication of cancer were enacted in four states. In Illinois new laws¹¹⁹ create in the department of health a division of cancer control and an advisory board to that division which is authorized to receive voluntary contributions from any source and to expend them for cancer control. An appropriation of \$25,400 was also made to enable the department of health to establish a cancer diagnostic service. In Wisconsin¹²⁰ provision was made for the annual appropriation of \$10,000 for research into the causes, prevention and cure of cancer. A new South Carolina law¹²¹ authorizes the state board of health to establish a standard for the conduct of cancer units in general hospitals, to provide financial aid to indigent cancer patients in such approved cancer units and to establish such facilities as it deems advisable to afford proper treatment and care. The board is also directed to carry on a proper educational program to prevent cancer, to aid in the early diagnosis of the disease and to inform hospitals and cancer victims concerning proper treatment. In Vermont¹²² a state cancer commission was created to be composed of the chairman of the cancer committee of the state medical society, two other members of the society and a layman. The commission is to establish and conduct cancer clinics throughout the state, which clinics are to furnish care to indigent cancer victims. The commission may grant state aid for care in any place in the state to afflicted persons who are not wholly indigent but are without means of providing adequate care for themselves. The names of persons receiving such aid may not be made public. An appropriation of \$10,000 was made to the commission for each of the next two years.

EXAMINATION OF PUBLIC SCHOOL PUPILS AND EMPLOYEES.—A new New Jersey law¹²³ requires every board of education periodically to determine or cause to be determined the presence or absence of communicable tuberculosis in pupils in schools under its jurisdiction. The state board of education is directed to promulgate rules and regulations with respect to the frequency and procedure of such examinations. Any pupil found to have tuberculosis in a communicable stage must be excluded from the school and can be

readmitted only when satisfactory evidence is adduced that he or she is free from communicable tuberculosis, is physically competent to engage in school activities and is not a menace to the health of other pupils. Another new New Jersey law¹²⁴ provides that in conducting the examinations of pupils required by law, the medical inspector may require pupils to loosen, open, or remove their clothing above the waist in a manner to facilitate inspection and examination, provided the parents or guardian are notified in writing of such proposed examination and the examination is conducted either in the presence of one of the parents or guardian or in the presence of a nurse or teacher. If the parent or guardian of a pupil objects to a proposed examination then the parent or guardian may file with the medical inspector a report of the family physician on the condition for which such examination was deemed advisable by the medical inspector. Still another new New Jersey law¹²⁵ authorizes every board of education to require a physical examination of all employees of the board at least once in three years, under such rules and regulations as the state board of education may promulgate. If the result of the examination indicates mental abnormality or a communicable disease, the employee is to be ineligible for further service until satisfactory proof of recovery is furnished.

Unsuccessful attempts were made in three states¹²⁶ to require all public school teachers to undergo annually a physical examination and to submit to blood tests to determine the presence or nonpresence of tuberculosis and venereal disease.

BUREAUS OR DIVISIONS OF INDUSTRIAL HYGIENE.—Idaho¹²⁷ and Montana¹²⁸ enacted laws this year establishing a bureau or division of industrial hygiene respectively in the department of public welfare and in the state board of health primarily to make studies of industrial hygiene, industrial health hazards and occupational disease problems in the state and to establish rules and regulations for the control and prevention of sickness in industry.

III. LEGISLATION REGULATING THE DISTRIBUTION OR POSSESSION OF DRUGS, FOODS, COSMETICS AND THERAPEUTIC DEVICES

NARCOTICS.—Unsuccessful attempts were made in five states¹²⁹ to repeal existing laws regulating the possession and distribution of narcotic drugs and to enact what appeared to be the uniform narcotic drug act. An unsuccessful attempt was made in Michigan¹³⁰ to repeal the uniform narcotic drug act enacted in 1937.

The uniform narcotic drug acts of Connecticut, Illinois, Indiana, Michigan, New Mexico, New York, Oregon, Rhode Island, Tennessee and West Virginia were so amended this year as either to redefine cannabis, which had previously been included in the act, or to redefine "narcotic drug" so as to include cannabis and to define the term "cannabis" substantially as follows:

"'Cannabis' shall include all parts of the plant *Cannabis sativa* L., whether growing or not; the seeds thereof; the resin

extracted from any part of such plant; and every compound, manufacture, salt, derivative, mixture or preparation of such plant, its seeds, or resin; but shall not include the mature stalks of such plant, fiber produced from such stalks, oil or cake made from the seeds of such plant, any other compound, manufacture, salt, derivative, mixture or preparation of such mature stalks (except the resin extracted therefrom), fiber, oil or cake, or the sterilized seed of such plant which is incapable of germination."¹³¹

Similar bills were killed in three states.¹³²

An unsuccessful attempt was made in Illinois¹³³ so to amend the uniform narcotic drug act as to increase the penalty that can be imposed for a violation thereof. Likewise, an unsuccessful attempt was made in Michigan¹³⁴ so to amend the uniform narcotic drug act as to provide that a physician may cause narcotic drugs to be administered by a nurse or intern under his direction. The present law provides that the physician may cause such drugs to be administered by a nurse or intern under his direction and supervision. A bill was killed in Texas¹³⁵ to amend the uniform narcotic drug act in force therein in several particulars.

The narcotic drug act in force in California was amended¹³⁶ by adding provisions authorizing the imprisonment of narcotic addicts as defined by the law. Another California amendment¹³⁷ contains details concerning prescriptions.

The governor of New Jersey vetoed a bill¹³⁸ proposing to authorize a judge of the court of common pleas, after notice and hearing, to commit a narcotic addict to any state, county or city institution for the care and treatment of his addiction.

Laws, other than narcotic drug acts, relating to marihuana were amended or supplemented in five states this year. A new Maine law¹³⁹ makes the prior law, which applied to the sale or distribution of cannabis applicable also to "any derivative of cannabis indica or cannabis sativa, either dried or in any cigarettes, tobacco, either smoking or chewing, or snuffing articles, or in any other form whatsoever." A new North Dakota law¹⁴⁰ amends the prior law relating to marihuana by defining marihuana to mean "all parts of the plant Cannabis sativa, and also known as American Hemp and Indian Hemp," and makes it unlawful for any person to grow, sell, trade, furnish, give away or to possess marihuana. The new law also makes it the duty of each sheriff to destroy all marihuana found growing on public highways or state or county lands. New Indiana and New Jersey laws¹⁴¹ require stated public officials to destroy marihuana weeds. A new Minnesota law¹⁴² permits Indian hemp to be grown for commercial purposes under license of the Commissioner of Agriculture.

An unsuccessful attempt was made in Montana¹⁴³ to amend the law prohibiting the distribution or possession of peyote (pellote), and anhalonium or any preparation thereof, so as to provide that the act should not apply to transporting, possessing or using peyote for religious sacramental purposes within the boundaries of an Indian reservation.

BARBITURIC ACID DERIVATIVES.—Laws prohibiting the sale or distribution of stated hypnotic or somnifacient drugs, except on the prescription of a licensed physician, dentist or veterinarian, were enacted in Connecticut,¹⁴⁴ Delaware,¹⁴⁵ Florida,¹⁴⁶ Georgia,¹⁴⁷ Minnesota,¹⁴⁸ Nevada,¹⁴⁹ New York,¹⁵⁰ North Carolina,¹⁵¹ South Carolina,¹⁵² Tennessee,¹⁵³ Vermont¹⁵⁴ and Washington.¹⁵⁵ All the laws referred to apply to the sale or distribution of barbital. The Delaware and New York laws also apply to the sale at retail of sulfonethymethane (trional), sulfonmethane (sulfonal), diethyl-sulfone, diethyl-methane (tetronal), paraldehyde, chloral or chloral hydrate and chlorbutanol. The Georgia law also applies to amytal, veronal, luminal or any similar drugs. The Minnesota and Vermont laws apply also to veronal, propional, ipral, dial, neonal, sandoptal, amytal, phenobarbital, phandom, noctal, allonal or medinal. The Washington law also applies to amytal, luminal, veronal, acid diethylbarbituric, para-amino-benzene sulfonamide, sulfanilamide, sulfamidyl, prontylin, prontosil, neoprontosil, neoprontylin, edimalin, sulfonamid or any salts, derivatives or compounds of any of the drugs mentioned.

Similar bills to restrict the sale or distribution of barbituric acid compounds to distribution on the written prescription of a licensed physician, dentist, or veterinarian were killed in Indiana¹⁵⁶ and Kansas.¹⁵⁷

A new Maine law¹⁵⁸ prohibits the retail distribution of veronal, or barbital, or any registered, trade-marked or copyrighted preparation registered in the United States Patent Office containing this substance, except on written prescription of a licensed physician, dentist or surgeon. The prior law seemed to permit the substance to be distributed on a written order of a physician, dentist or veterinarian or if dispensed by a licensed pharmacist. The prior law contained no limitation on the distribution of a registered, trade-marked or copyrighted preparation registered in the United States Patent Office containing the aforementioned substance unless the preparation contained more than 40 grains of the drug to the avoirdupois or fluid ounce.

A somewhat similar bill was killed in California.¹⁵⁹

SULFANILAMIDE.—Laws prohibiting the retail distribution of sulfanilamide except on the written prescription of a licensed physician, dentist or veterinarian were enacted in California,¹⁶⁰ Connecticut,¹⁶¹ Florida,¹⁶² Nevada,¹⁶³ North Carolina,¹⁶⁴ Pennsylvania,¹⁶⁵ Vermont¹⁶⁶ and Washington.¹⁶⁷

A similar bill was killed in Colorado.¹⁶⁸

144. Conn., Laws, 1939, c. 364.

ORGANIZATION SECTION

881

DINITROPHENOL.—A new California law ¹⁶⁹ makes it a felony for any person to sell, dispense, administer or prescribe dinitrophenol for the purpose of human consumption. Laws prohibiting the retail distribution of dinitrophenol except on the prescription of a licensed physician, dentist or veterinarian were enacted in Connecticut, ¹⁶¹ Florida, ¹⁶² Nevada ¹⁶³ and North Carolina. ¹⁶⁴

CINCOPHEN.—Laws prohibiting the retail distribution of cincophen except on the written prescription of a licensed physician, dentist or veterinarian were enacted in California, ¹⁷⁰ Connecticut, ¹⁷¹ Florida, ¹⁷² Nevada, ¹⁷³ North Carolina ¹⁷⁴ and Vermont. ¹⁷⁵

AMINOPYRINE.—Laws prohibiting the retail sale or distribution of aminopyrine except on the written prescription of a licensed physician, dentist or veterinarian were enacted in California, ¹⁷⁶ Connecticut, ¹⁷⁷ Florida, ¹⁷⁸ Nevada, ¹⁷⁹ North Carolina ¹⁸⁰ and Vermont. ¹⁸¹

DIPHENYLAMINE.—A new California law ¹⁸² makes it a felony to sell, dispense, administer or prescribe diphenylamine for any purpose.

MISCELLANEOUS DRUGS.—An unsuccessful attempt was made in North Carolina ¹⁸³ to provide that all medicinal preparations, whether proprietary, patented or sold on prescription, containing acetanilide or any of the bromides, must be marked "poison" on their containers. The Connecticut House killed a bill ¹⁸⁴ proposing to prohibit the sale or distribution of dangerous caustic or corrosive substances unless in containers bearing a conspicuous, easily legible label or sticker containing (a) the name of the article; (b) the name and place of business of the manufacturer, packer, seller or distributor; (c) the word "POISON" in letters of not less than 24 point size and (d) directions for treating a case of accidental personal injury. A bill was referred to the next session of the legislature in Massachusetts ¹⁸⁵ which proposed to prohibit the sale of any medicine "which in and of itself contains enough poison or other deadly drug so that if taken in whole or in part is sufficient to cause the death of the person taking it" unless the container is labeled so as to state the nature of the poison or the deadly drug, what quantity thereof would constitute a lethal dose, and the antidote therefor.

FOODS, DRUGS, COSMETICS AND THERAPEUTIC DEVICES.—Laws were adopted in California, ¹⁸⁶ Connecticut, ¹⁸⁷ Florida, ¹⁸⁸ Indiana, ¹⁸⁹ Nevada, ¹⁹⁰ New Jersey, ¹⁹¹ New York ¹⁹² and North Carolina, ¹⁹³ repealing prior laws relating to food and drugs and enacting so-called uniform food, drug, cosmetic and device acts to regulate the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and therapeutic devices. These new laws in general correspond with the provisions of the Federal Food, Drug, and Cosmetic Act of 1938.

Similar bills failed of passage in twenty states. ¹⁹⁴

Amendments to existing laws relating to foods and drugs were enacted in Arkansas, ¹⁹⁵ Georgia, ¹⁹⁶ Missouri ¹⁹⁷ and Oklahoma. ¹⁹⁸

Similar bills were killed in three states. ¹⁹⁹

A new law in Wyoming ²⁰⁰ prohibits the sale of adulterated and misbranded cosmetics.

A somewhat similar bill was killed in Pennsylvania. ²⁰¹ An unsuccessful attempt was made in North Dakota ²⁰² to amend the existing law relating to the sale and distribution of cosmetics.

An unsuccessful attempt was made in Michigan ²⁰³ to enact a new law relating to the manufacture, sale, distribution and advertising of foods.

IV. LEGISLATION RELATING TO LICENSES TO PRACTICE THE HEALING ART

A. Conditions Precedent to Licensure Imposed Alike on All Applicants, Nonsectarian or Cult

KNOWLEDGE OF THE BASIC SCIENCES.—Basic science laws were enacted in Florida ²⁰⁴ and South Dakota ²⁰⁵ which will require all applicants for licenses to practice any form of the healing art to demonstrate to a board of examiners a comprehensive knowledge of anatomy, chemistry, physiology, pathology and bacteriology before presenting themselves to their respective licensing boards for examination and licensure. The Florida board is to consist of five members learned in the basic sciences, selected from the faculties of the universities and colleges in Florida having four year college courses. On the other hand, the South Dakota board is to have a composite membership, one doctor of medicine, one osteopath, one chiropractor and two members who are to be full time professors or associate or assistant professors teaching the subject of the basic sciences in any university or college in the state accredited by the North Central Association of Secondary Schools and Colleges and who do not hold a degree in any of the healing arts.

Basic science bills were considered and killed in Georgia, ²⁰⁶ Missouri, ²⁰⁷ New Mexico, ²⁰⁸ North Dakota ²⁰⁹ and Rhode Island. ²¹⁰

A self-styled "basic science" bill was killed in South Dakota. ²¹¹ The bill was a basic science act in no reasonable sense of the term. It proposed to prohibit the medical board, the chiropractic board or the osteopathic board from admitting to examination any applicant who had not passed a satisfactory examination in the basic sciences named. However, instead of such applicants being examined by an impartial board in the subjects enumerated examinations in those subjects were to be given by the medical, chiropractic or osteopathic boards "to applicants for license in their respective professions."

An unsuccessful attempt was made so to amend the basic science act of Minnesota²¹² as to permit certain chiropractors to receive a certificate of registration in the basic sciences on application to the board. The Wisconsin assembly also killed a bill²¹³ which proposed in effect that chiropractic applicants submitting to the basic science examination should be examined by chiropractors designated by the state board of examiners of chiropractic.

CENTRAL LICENSING AGENCY.—Unsuccessful attempts were made in Connecticut²¹⁴ and Maine²¹⁵ to create a central licensing agency to exercise all the powers and functions heretofore vested in the secretaries of the various licensing boards of the state, including the medical examining board, the osteopathic board, the chiropractic board, the dental board and others.

B. Changes in Medical Practice Acts Affecting Nonsectarian Practitioners

BOARDS OF MEDICAL EXAMINERS.—*Composite Membership.*—Legislation was enacted in Georgia²¹⁶ and Massachusetts²¹⁷ repealing provisions in prior laws which, in effect, required representation on the board for various schools of medical practice. By the new Georgia law the board is to consist of ten physicians of any school of medical practice. The prior law required five members of the board to be regular physicians, three to be eclectic physicians and two to be homeopathic physicians. The new Massachusetts law struck out the provision in the prior law that no more than three members of the board of registration in medicine should at any one time be members of any one chartered state medical society.

An unsuccessful attempt was made in Oklahoma²¹⁸ to strike out the provision in the present law which requires one member of the board of medical examiners to be a physiomedic physician. A bill was killed in Massachusetts²¹⁹ also to require that two members of the board of registration in medicine be osteopaths.

Right of State Medical Society to Nominate Members.—A new Oregon law²²⁰ requires the Oregon State Medical Society on or prior to February 1 annually to nominate and certify to the governor the names of three qualified physicians to succeed the board member whose term expires that year. The governor, however, in making the required appointment is not restricted to the list so certified but may, if he so chooses, appoint any other physician "having the necessary qualifications." The law further provides that "present board members shall be deemed and taken to have been so certified by the said society."

Separate Eclectic Boards.—A bill was killed in Connecticut²²¹ which, if enacted, would have reestablished an eclectic board of medical examiners.

Board Meetings.—A new Alabama law²²² authorizes the board to fix the time at which examinations are to be held annually. The prior law required the board to give not less than two examinations annually. The new Oregon law²²³ previously referred to also requires the board to hold meetings for the examination of applicants for licenses on the second Tuesday, Wednesday and Thursday in January and the third Tuesday, Wednesday and Thursday in June of each year in

Portland and permits the board to hold special meetings for the examination of applicants for licenses in the same manner as other special meetings of the board are called.

Power to Reinstate Revoked License.—Laws adopted in New Jersey²²⁴ and Oregon²²⁵ permit the boards in question in their discretion to relicense without reexamination any person whose license to practice has been suspended or revoked.

Power to Regulate Conduct of Licentiate.—A new Delaware law²²⁶ authorizes the medical council to promulgate regulations "for the proper supervision and control of the professional conduct of all persons under its jurisdiction."

Power to Issue Subpoenas and Administer Oaths.—The new New Jersey law²²⁷ authorizes the secretary of the board, as well as the president, on whom alone the prior law conferred the powers to be referred to, (1) to issue subpoenas and (2) to administer oaths. A person refusing to appear in response to such a subpoena, or who, after appearing, refuses to be sworn or to testify is to be liable to a penalty of \$50. A new Tennessee law²²⁸ grants the president and secretary of the board in revocation or suspension proceedings power to administer oaths, issue subpoenas and to compel the attendance and testimony of witnesses.

CONDITIONS PRECEDENT TO LICENSURE.—*Educational Qualifications.*—Laws imposing educational qualifications in addition to those required by the prior laws on applicants for licenses to practice medicine were enacted in Ohio,²²⁹ Oregon²³⁰ and Texas.²³¹ The Ohio, Oregon and Texas laws, among other things, require, in effect, that applicants prior to their admission to medical school must have had at least two years premedical education in an approved college or university. The Oregon law provides, in addition, that an applicant must have graduated from a medical school or college on the approved list of the Council on Medical Education and Hospitals of the American Medical Association and must have completed an internship of at least one year in a hospital approved for internship training by the American Medical Association. The Texas law provides that an applicant must be a graduate of a bona fide reputable medical school which maintains a course of instruction of not less than four terms of eight months each, which offers courses of instruction in anatomy, physiology, chemistry, histology, pathology, bacteriology, diagnosis, surgery, obstetrics, gynecology, hygiene and medical jurisprudence and possesses and utilizes laboratories, equipment and facilities for proper instruction in all the subjects named. The Ohio law also requires applicants for licenses by reciprocity to possess the minimum educational qualifications exacted of applicants for licenses after examination.

The new New Jersey law²³² previously discussed also altered somewhat the educational qualifications required of applicants. Hereafter applicants must prior to the receipt of their professional diploma or degree have studied not less than four full school years, including four satisfactory courses of at least eight months

232. N. J., Laws, 1939, c. 115.

(rather than *seven* months as the prior law required) in some school of medicine or osteopathy in good standing in the opinion of the board, "which courses shall have included a thorough and satisfactory course of instruction in medicine and surgery." The prior law also required an acceptable internship. The new law requires an internship "or in lieu thereof" completion of "one year of postgraduate work acceptable to the board in a school or hospital approved by the board." Before an applicant begins his internship training in New Jersey or the alternative postgraduate study the law now requires him to obtain from the board a certificate of qualification and to present that certificate when he applies for a license. This new law also permits a person licensed to practice osteopathy to be examined and licensed prior to Nov. 1, 1941, to practice medicine and surgery on showing completion of an internship *acceptable to the board* in a hospital approved by the board or the completion of a postgraduate course of two years *acceptable to the board* in a college of osteopathy approved by the board, the changes effected by the new law being indicated by the italicized phrases.

A new California law²³³ so amends the prior medical practice act as to make no differentiation with respect to the requirements for licensure between graduates of Canadian medical schools approved by the board of medical examiners and graduates of approved American medical schools.

A bill was killed in Missouri²³⁴ to require applicants, in addition to existing educational qualifications, to have completed a premedical education consisting of a minimum of sixty semester hours of college credit in acceptable subjects from a reputable college or university approved by the board.

Citizenship Requirements.—Laws were adopted in Arkansas,²³⁵ Georgia,²³⁶ New Hampshire,²³⁷ New Jersey²³⁸ and Texas²³⁹ restricting licensure in medicine to citizens of the United States. A similar bill would have become law in California but for the pocket veto of the governor.²⁴⁰

Similar bills were considered and killed in Colorado²⁴¹ Connecticut,²⁴² Illinois²⁴³ and New York.²⁴⁴

Laws were enacted in Illinois,²⁴⁵ Massachusetts²⁴⁶ and New Mexico²⁴⁷ restricting licensure in medicine to citizens of the United States or to persons who have legally declared their intention of becoming such citizens.

A similar bill was killed in Massachusetts.²⁴⁸

In codifying the statutes of South Dakota, the code commissioners added to the provision of the medical practice act requiring an applicant to be a citizen of the United States a qualifying phrase "or a person who has declared his intention to become a citizen." The code as so worded was adopted by the legislature.²⁴⁹

Examination.—Laws were enacted in New Jersey and Texas relating to the examination to be given

applicants for licenses to practice medicine. The New Jersey law²⁵⁰ changes the provisions of the prior law listing the subjects in which applicants are examined, substituting "pharmacology" for "materia medica" and "diagnosis, including diseases of the skin, nose and throat" for "practice of medicine, including diseases of the skin, nose and throat." The Texas law²⁵¹ eliminates provisions in the prior law which permitted the examination to be taken in a language other than English. The new Texas law also requires applicants for a license by reciprocity to pass an oral examination "in practical subjects as may be prescribed by the board." The new New Jersey law also provides a fee for reexamination of \$25, the prior law not providing a fee for reexamination.

Licensure Without Examination.—Laws were enacted in New Jersey²⁵² and Ohio²⁵³ permitting the licensing without examination of diplomates of the National Board of Medical Examiners. The provisions of the Texas medical practice act permitting the licensing without examination of applicants licensed in other states was so amended this year as to limit such licensure to citizens of the United States and to licentiates of other states which accord a similar privilege to Texas licentiates. The new Texas law also (1) provides that such applicants must pass an oral examination in practical subjects prescribed by the board and (2) prohibits the issuance of a license by reciprocity to an applicant who does not hold a license from another jurisdiction giving him the same right to practice medicine in that jurisdiction as a license to practice medicine in Texas. A new Arkansas law²⁵⁴ permits the board to license without examination any honorably discharged medical officer of the United States Army, Navy or public health service, who has been licensed to practice in some other state of the union after examination, who has qualified under the basic science act of Arkansas, who has been a resident of the state for one year or more and who is a citizen of the United States.

REVOCATION, SUSPENSION OR REFUSAL OF LICENSES.
—Right to Suspend.—A new Delaware law²⁵⁵ authorizes the medical council to suspend, as well as to refuse to issue or revoke licenses to practice. So far as specific language is concerned, the prior law limited the council's authority in this respect to refusing to license or to revoking a license.

Causes.—Laws setting out grounds for the suspension, revocation or refusal of licenses, in addition to the causes or grounds stated in prior medical practice acts, were enacted in Arkansas, California, Delaware, New Jersey, Oregon and Texas. The new Arkansas law²⁵⁶ authorizes the board to refuse to grant or to revoke a license if the applicant or the holder is not an American citizen. The new California law²⁵⁷ makes it unprofessional conduct, which is a cause for revocation or suspension, for a licentiate knowingly to sign any certificate or other document required by law which falsely represents the existence or nonexistence

of a state of facts. The Delaware law²⁵⁸ makes the following additional grounds for the refusal to license or for the suspension or revocation of a license: (a) chronic drug addiction or (b) violation of regulations adopted by the medical council for the supervision and control of professional conduct. The New Jersey law²⁵⁹ sets forth the following as additional causes for disciplinary action: (a) adjudication of insanity; (b) habitual use of drugs or intoxicants; (c) fraudulent advertising; (d) employing unlicensed persons to perform work which can legally be done only by persons licensed to practice medicine in the state; (e) conviction of a violation of any federal or state law relating to narcotic drugs. The additional grounds set out by the new Oregon law²⁶⁰ consist of (a) "such conduct as would not be indulged in by an ethical physician and surgeon under all the circumstances, taking into consideration the good of the patient and public, the time and place"; (b) making false or misleading statements regarding the licentiate's skill or the value of his medicine, treatment or remedy in the treatment of any disease or other abnormal condition of the human mind or body, or (c) advertising or holding one's self out to treat diseases or other abnormal conditions of the human body by any secret formula, medicine, method, treatment or procedure. Several additional grounds are set out in the new Texas law,²⁶¹ among them being (a) the use of any advertising statement of a character tending to mislead or deceive the public; (b) advertising professional superiority, or the performance of professional service in a superior manner; and (c) employing directly or indirectly any person whose license to practice has been suspended, or association in the practice of medicine with any person whose license to practice has been suspended or any person who has been convicted of the unlawful practice of medicine in Texas or elsewhere.

Unsuccessful attempts were made in four states to provide grounds for the revocation or suspension of licenses, in addition to the grounds now stated in present medical practice acts.²⁶²

Procedure.—Laws relating to the procedure to be followed in revocation or suspension proceedings were adopted in five states. A new Delaware law²⁶³ permits the medical council to act on its own motion as well as on complaints in writing made to it. A New Jersey law²⁶⁴ provides that in such proceedings against a licentiate because of the licentiate's conviction of a crime involving moral turpitude or of violating any federal or state law relating to narcotic drugs, the accused physician need not be furnished with a copy of the complaint nor need he be given a hearing. A new Oregon law²⁶⁵ specifies in detail the procedure the board must follow in revoking or suspending a license. In brief, the law requires that before the board can institute proceedings there must be filed with it a complaint under oath setting forth the facts on which the charge is based, which complaint must be filed not later than three years after the commission of the acts complained of. The board must then serve on the accused physician a written notice, stating the time and place of the hearing on those charges, together with a copy of the complaint. At

the hearing, the accused and his attorney shall have ample opportunity to present a defense, including the right to subpoena witnesses and necessary documents, and a stenographic report of the proceedings must be made. The practice in such proceedings must conform as nearly as practicable to equity suits. In Tennessee a law was enacted²⁶⁶ which provides that in such proceedings the affected licentiate must be given fifteen days' notice to prepare for a hearing and at the hearing he is entitled to be heard in person or by counsel or both. The board is given the power to make all needed procedural rules for such hearings and to employ an attorney to represent it. In Texas a new law²⁶⁷ amends the corresponding provisions of the prior law so as to provide that in instituting a disciplinary proceeding the appropriate district or county attorney, whom the law authorizes to prosecute such proceedings, must file with the appropriate court a complaint in writing, stating the grounds of the proceeding and signed officially by the prosecuting official instituting it.

Unsuccessful attempts were made in Arkansas,²⁶⁸ California²⁶⁹ and Oklahoma²⁷⁰ to amend the provisions of the medical practice acts relating to the procedure to be followed in revocation proceedings or appeals therefrom. Of most interest is one of the Oklahoma bills,²⁷¹ which proposed that a licentiate appealing from an order of revocation or suspension might appeal to the district court of the county of his residence, which was to try the case de novo, and that no decision of the board's revoking or suspending a license should become final "pending final decision of the Supreme Court of this State."

ANNUAL REGISTRATION.—Unsuccessful attempts were made in Indiana,²⁷² Massachusetts,²⁷³ Missouri²⁷⁴ and Oklahoma²⁷⁵ to require the annual registration of physicians and the payment of an annual registration fee. An unsuccessful attempt was made in Utah²⁷⁶ to raise to \$10 the annual license renewal fee required of physicians and surgeons, osteopaths, chiropractors and dentists.

RECORDING OF LICENSES.—The Wisconsin law requiring a licensed physician to record his license with the county clerk of the county in which he resides was so amended this year²⁷⁷ as to require nonresident physicians to file their Wisconsin licenses with the county clerk in each county in which they practice.

POSTING OF NAMES AT ENTRANCE TO OFFICE.—A new New Jersey law²⁷⁸ requires every person practicing medicine under a firm name and every person practicing medicine as an employee of another to cause his name to be conspicuously displayed and kept in a conspicuous place at the entrance of the place where such practice is conducted. Failure to comply with this requirement subjects the offender to a penalty of \$100.

INTERNS AND RESIDENT PHYSICIANS.—A new Idaho law²⁷⁹ permits "students who have had training in recognized medical colleges in good standing and who are performing the duties of an intern in . . . any duly organized hospital . . . operating under the supervision of a medical staff" freely to perform their

duties without an examination or the issuance of a license to practice medicine. An amendment adopted to the California medical practice act this year²⁸⁰ authorizes any graduate student registered with the board of medical examiners and on whom a degree of Doctor of Medicine, Bachelor of Medicine, or Doctor of Osteopathy has been conferred and any regularly matriculated student in a school approved by the board to register with the board and to be permitted for a period not to exceed two years to treat the sick and afflicted either as a student in the school or as an intern in a hospital approved for the training of interns. Such persons so registered may for rendering treatment receive compensation from the hospital or school concerned. Except as authorized by this amendment, no graduate student may treat the sick or afflicted or receive compensation therefor. A new New Jersey law²⁸¹ limits the exemption from the medical practice act accorded to members of the resident staffs of charitable or municipal hospitals or asylums by providing that the exemption shall not apply with respect to an individual after he has served as a resident physician for a total period of two years and that the exemption applies only with respect to an individual who has received from the board a certificate of qualification prior to serving in such capacity.

A bill was killed in Maryland²⁸² proposing that any person shall be regarded as practicing medicine who receives compensation from the state for the treatment of patients in private or public mental hospitals, including resident or assistant resident physicians.

ACTS CONSTITUTING THE PRACTICE OF MEDICINE.—A new Texas law²⁸³ provides that the medical practice act is to apply to persons, other than registered pharmacists not pretending to be physicians, who offer for sale in public places contraceptives, prophylactics or remedies which they recommend for the cure of disease.

A bill, killed in Iowa,²⁸⁴ proposed that any person, firm, association or corporation acting in any manner as an agency for bringing a licensee and patient together or unlawfully employing, arranging with or by subterfuge procuring the services of a licensed practitioner shall be deemed to be practicing medicine, osteopathy, chiropractic, dentistry, optometry or podiatry, as the case might be, without a license. The Maryland legislature, as previously noted, killed a bill²⁸⁵ which proposed that any person should be regarded as practicing medicine who should receive compensation from the state for the treatment of patients in private or public mental hospitals, including resident or assistant resident physicians. An unsuccessful attempt was made in Massachusetts²⁸⁶ to provide that the term "practice of medicine" or "rendering medical service," as used in the medical practice act, should include "any examination or treatment of a human being, by the use or misuse of any means, for the purpose of diagnosing, preventing or curing any deviation from normal condition of mind or body, or for the purpose of relieving any condition of mind or body whether arising from such a deviation or otherwise." A bill was likewise killed in Nevada²⁸⁷ to make it unlawful for any person to practice medicine, surgery, *anesthesia* or obstetrics without being licensed by the board of medical examiners. The present law does not specifically prohibit the practice of anesthesia by persons not licensed by the board of medical examiners. An effort failed in Texas²⁸⁸ to make it unlawful for any person other than a licensed physician to offer for sale any truss or

other mechanical device commonly used for the relief of rupture or hernia except on the written prescription of a licensed physician. The bill also proposed to make it unlawful for any person other than a licensed physician to offer to fit any such truss or mechanical device. A bill died in the senate of Washington²⁸⁹ to make it unlawful for any person operating a bathhouse, massage parlors or similar establishments to furnish by himself or by an agent any bath, massage or other treatment or to attempt to treat any disease, injury or condition of health, unless the person so doing is licensed to practice one of the healing arts authorized by the laws of the state.

A bill was killed in Connecticut²⁹⁰ to prohibit the sale of any arch support, braces or other foot and leg appliances except on the prescription of an orthopedic surgeon or of the state health commissioner. An unsuccessful attempt was made in Missouri²⁹¹ to prohibit the sale, prescribing or fitting of any hearing aid device except by a licensed physician or on his prescription.

PERSONS OR ACTS EXCEPTED FROM THE PROVISIONS OF THE MEDICAL PRACTICE ACT.—*Christian Scientists.*—The provisions of the Texas medical practice act providing that nothing therein shall "effect or limit in any way the application or use of the principles, tenets or teachings of any church in the ministration to the sick or suffering by prayer without the use of any drug or material remedy, provided sanitary and quarantine laws and regulations are complied with" and that no charge is made therefor, directly or indirectly was amended this year²⁹² by (1) eliminating the phrase italicized and (2) by adding the following phrase "and provided, further, that all those so ministering or offering to minister to the sick or suffering by prayer shall refrain from maintaining offices, except for the purpose of exercising the principles, tenets, or teachings of the church of which they are bona fide members." The effect of this amendment would seem to be to permit such practitioners legally to charge for their services.

Unsuccessful attempts were made in Ohio²⁹³ and West Virginia²⁹⁴ to provide that the provisions of the medical practice act should not be construed to apply to the practice of Christian science, provided that the laws, rules and regulations relating to communicable diseases and sanitary matters were not violated.

General.—The provisions of the New Jersey medical practice act which exempted therefrom a commissioned surgeon or physician of the United States Army, Navy or Marine hospital service were so amended this year²⁹⁵ as to require a person claiming such an exemption to be actively engaged in the performance of his official duties and by stating specifically that this exemption does not apply to reserve officers or national guard officers. This law also specifically exempts "a graduate physiotherapist . . . electro-therapist, or hydro-therapist, while operating in each particular case under the specific direction of a regularly licensed physician or surgeon. This exemption shall not apply to such assistants of persons who are licensed as osteopaths, chiropractors, optometrists or other practitioners holding limited licenses." Additional provisions of this law which place restrictions and limits on the exemption granted in favor of resident physicians have previously been noted.

280. Calif., Laws, 1939, c. 341.

281. N. J. Laws, 1939, c. 115.

282. Md. H. 754.

283. Tex., Laws, 1939, c. —, approved March 15, introduced as

H. 148 (a companion bill S. 74 was killed in the senate).

284. Iowa H. 543.

285. Md. H. 754.

286. Mass. S. 258.

287. Nev. S. 70.

291. Mo. H. 182.

292. Tex., Laws, 1939, c. —, approved March 15, introduced as H. 148. Other bills proposing to accomplish approximately the same purpose were also before the Texas legislature (S. 26, H. 10, S. 74) but were not enacted.

293. Ohio H. 392.

294. W. Va. S. 152.

295. N. J. Laws, 1939, c. 115.

Interns.—There has been previous discussion with respect to the exemptions granted interns by laws enacted in California, Idaho and New Jersey.

Alien Physicians.—Two bills were withdrawn from the consideration of the Wisconsin legislature²⁹⁶ which proposed a method by which "fifty medical physicians who may have been engaged in the actual practice of medicine or surgery in Germany, Austria, Czechoslovakia or Poland" might be permitted to practice in the state without conforming to the requirements of the medical practice act.

ENFORCEMENT PROVISIONS.—*Use of the Injunctive Process.*—A new New Jersey law²⁹⁷ authorizes the court of chancery at the suit of the Attorney General or of the board of medical examiners to restrain the unlicensed practice of medicine and various other violations of the medical practice act.

Bills to permit courts to enjoin the unlicensed practice of medicine failed of enactment in California,²⁹⁸ Missouri,²⁹⁹ New York³⁰⁰ and North Dakota.³⁰¹

Penalties.—Laws amending the penalty provisions of medical practice acts were enacted in Arizona, New Jersey, Oregon and Texas. The Arizona law³⁰² makes it a felony to practice or attempt to practice medicine without having a valid recorded license so to practice issued by the state board of medical examiners. The prior law made it a felony to practice or attempt to practice without having a valid recorded certificate. The New Jersey law³⁰³ authorizes the imposition on a person convicted for the second time of violating the medical practice act of a penalty of \$500. If a defendant so convicted fails to pay the penalty, the court is authorized to commit him to jail for not less than thirty days nor more than two hundred days. The new Oregon law³⁰⁴ makes it mandatory on the court to sentence a defendant, convicted for the second or subsequent time of a misdemeanor under the medical practice act, to the county jail for not less than ten days, in addition to whatever other fine or imprisonment is permitted by the medical practice act. The new Texas law³⁰⁵ reduces to thirty days the maximum imprisonment that can be imposed on a person convicted of practicing medicine without a license. As the law now reads, a person convicted of practicing without a license is guilty of a misdemeanor and is to be punished by a fine of not less than \$50 nor more than \$500 and by imprisonment in the county jail for not more than thirty days.

An unsuccessful attempt was made in New Jersey³⁰⁶ to increase the penalty to be imposed on persons convicted of practicing without a license.

Miscellaneous.—Among other things, the amendments to the Texas medical practice act enacted this year,³⁰⁷ referred to in several connections heretofore, eliminated the provisions in the prior law that permitted the board to license applicants to practice obstetrics alone. By a new Ohio law³⁰⁸ the fines collected for violations of the medical practice act are to be distributed one half to the board of medical examiners

and one half to the county or municipality in which the offense was committed.

A bill was killed in Arkansas³⁰⁹ to make it unlawful for a physician to practice under any name except his own true name or to operate, treat, practice, manage or be employed in any room, office, hospital or clinic where medical treatment is administered or done under the name of any unlicensed person, corporation, company, association or trade name; or to assist or aid in any manner any unlicensed person to practice medicine.

C. Changes in Cult Licensing Laws

OSTEOPATHS.—Amendments were adopted this year in Delaware, Florida, Maine, New Jersey, New York, Oklahoma and Tennessee to the laws relating to the practice of osteopathy in force in those states.

Probably most important is the new Tennessee law,³¹⁰ which extensively amended the prior osteopathic practice act and which without doubt grants to osteopaths now licensed and to be licensed in the future the right to practice medicine and surgery without restriction. Specifically, the new law states that a license to practice osteopathy in any county in this state, in all its branches, as taught and practiced by the recognized associated colleges of osteopathy, with the right to use such drugs as are necessary in the practice of osteopathy, surgery, and obstetrics, including narcotics, antiseptics, anesthetics, and biologicals." The law further provides that osteopaths shall observe and be subject to all state and municipal regulations relating to the control of contagious diseases, the reporting and certifying of births and deaths and all matters pertaining to public health, and such reports must be accepted by the officer or department to whom they are made, equally with the reports of physicians of any other school of medicine.

The new New York law³¹¹ provides that any licensed osteopath or any applicant for such a license "who upon the submission of proper credentials or by examination satisfies the regents that he has received sufficient instruction and training, may be granted the right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biological products."

The new Delaware law provides that (1) osteopathic applicants are to be examined by the medical council and an osteopath designated by the Delaware State Osteopathic Society; (2) such applicants must be examined in the subjects enumerated in the prior law and in addition "Therapeutics"; and (3) such applicants must present evidence, in addition to the qualifications as now required by law, that they have completed two years of acceptable college work, including English, physics, chemistry and biology, and have served as interns for one year in hospitals recognized by the American Osteopathic Association or by the American Medical Association.³¹²

The new Florida law³¹³ requires licensed osteopaths to register annually on or before January 1 with the osteopathic board and at that time to pay annual registration fees of \$5 and to condition the renewal of a license to practice osteopathy on the presentation by the holder thereof of evidence that in the preceding year the licentiate has attended the two day educational program as conducted by the Florida osteopathic association, or its equivalent as approved by the board of osteopathic examiners.

312. Del. Laws, 1939, c. —, approved March 3, introduced as H. 33

313. Fla. Laws, 1939, c. 19, 20.

The new Maine law³¹⁴ requires osteopaths to renew their licenses annually and to pay an annual renewal fee of \$2 and to condition annual renewal on the presentation to the board by each licensee of satisfactory evidence that he has attended at least two days of the annual educational program conducted by the state osteopathic association, or its equivalent, to the approval of the board in the preceding year.

One new New Jersey law³¹⁵ defines osteopathy to "include the diagnosing, treating, operating or prescribing for any human disease, pain, injury, deformity, mental or physical condition; provided, however, that a license to practice osteopathy shall not permit the holder thereof to prescribe, administer or dispense drugs for internal use in the treatment of any human ailment, disease, pain, injury, deformity, mental or physical condition or to perform such surgical operations as require cutting." Another new New Jersey law³¹⁶ provides that any person holding a valid license to practice osteopathy within the state shall be authorized to continue to practice osteopathy, as just defined, pursuant to said license, as though the act under which said license had been issued had not been repealed. The latter law apparently was necessary because the extensive amendments to the medical practice act adopted in 1937, which eventually will confer on osteopaths the right to practice medicine and surgery without restriction, left in doubt the right of osteopaths licensed in the past to continue to practice osteopathy in the limited form just noted.

The new Oklahoma law³¹⁷ requires licensed osteopaths to register annually with the state board of osteopathic examiners, to pay annual licensing fees of \$2 and to condition the renewal of such a license on the submission of proof that the licensee has attended at least two days of the annual educational program conducted by the Oklahoma State Osteopathic Association in the year preceding application for renewal.

Two unsuccessful attempts were made in Illinois³¹⁸ to enact a separate osteopathic practice act and to create an independent examining committee to examine and license persons to practice osteopathy, which the bills proposed to define as "a system of practice of the healing arts in all its branches with therapeutics majoring in manipulation." Unsuccessful attempts were made in eleven states to amend existing laws relating to the practice of osteopathy.³¹⁹ Bills rejected in Kansas, if enacted, would have granted a licensed osteopath the right to practice osteopathy in all its branches, which, the bill stated, includes "operative surgery with instruments, physiotherapy and the use of drugs, as taught and practiced in the legally incorporated colleges of osteopathy of good repute, and the right to register under the laws of the United States of America governing narcotics." The Connecticut and Oregon bills proposed to extend the scope of a license to practice osteopathy by permitting a licensee to practice osteopathy as taught in the branches and embraced in the subjects covered by the examinations provided by the bills, which might have indicated that a licensee could practice surgery and obstetrics. In addition, the Oregon bill proposed to deprive the board of medical examiners of their present jurisdiction in examining and licensing osteopaths and would have established an independent board of osteopathic examiners. The Ohio and South Dakota bills specifically would have permitted the examining boards to license osteopaths to practice surgery.

CHIROPRACTORS.—Amendments to laws regulating the practice of chiropractic were adopted in Connecticut,³²⁰ Delaware,³²¹ Georgia,³²² New Hampshire,³²³ New Jersey,³²⁴ South Dakota,³²⁵ Tennessee³²⁶ and Wyoming.³²⁷ Of greatest interest is the new New Jersey law, which repealed all provisions in the prior law which permitted the issuance of limited licenses to chiropractors. Until July 31, 1944, persons graduating from chiropractic schools subsequent to 1921 may be licensed to practice chiropractic, which is defined as "the detecting and adjusting, by hand only, of vertebral subluxations." Thereafter chiropractic applicants must possess the same educational qualifications as physicians and surgeons and will receive identical licenses. Until Jan. 1, 1940, persons graduating from chiropractic schools prior to 1921 may be licensed to practice chiropractic as just defined.

The new Connecticut and Georgia laws require chiropractors to renew their licenses annually with the board and condition that renewal on attendance at at least one of the two day "educational" programs conducted by the state chiropractic association during the preceding year. In addition, the Georgia bill requires applicants for licenses to practice chiropractic to have graduated from chiropractic schools, which require for graduation a period of active attendance equivalent to a standard four year college course instead of the past requirement that such applicants have graduated from chiropractic schools requiring a course of three years of six months each. The new Delaware law amends the prior chiropractic act so as to authorize the board of chiropractic examiners to refuse to issue or to reissue a license for any of the following causes: material misrepresentation of facts in applications to practice; chronic and persistent inebriety or chronic drug addiction; the practice of criminal abortion; public advertising of special ability to cure chronic incurable diseases; and the presentation to the board of examiners of licenses that had been illegally obtained or have been signed or issued unlawfully or under fraudulent representation. The Delaware law also prohibits the issuance of an occupational license by the state for the practice of chiropractic unless the applicant has first procured from the board of examiners a certificate required by the chiropractic practice act. The new New Hampshire law limits licensure to citizens of the United States or of a Canadian province in which a like privilege is granted to citizens of the United States.

The new South Dakota law (1) provides that the practice of chiropractic "shall be limited to the methods of practice as taught in the standard colleges of chiropractic recognized by the state board of chiropractic examiners," thus replacing provisions in the prior law which limited the practice of chiropractic to "the adjustment by hand of the articulations of the human spine and other incidental adjustments according to the science of chiropractic" and specifically prohibited chiropractors from practicing obstetrics or treating contagious or infectious diseases; (2) requires chiropractic applicants to be examined in anatomy, bacteriology, physiology, chemistry, pathology, histology, gynecology, symptomatology, hygiene and public health, diagnostic x-ray and principles and practice of

chiropractic, and (3) requires an applicant to have acquired a high school education and to be a graduate of an approved chiropractic school, which requires for graduation a period of actual attendance equivalent to the standard four year college course, teaching adequate courses in the basic sciences and all subjects pertaining to the practice of chiropractic.

The new Tennessee law³²⁸ (1) makes eligible for examination and licensure any applicant who is of good moral character, who has a preliminary school education equal to that of a standard accredited high school and who is a graduate of a school of chiropractic giving adequate courses in anatomy, physiology, symptomatology, spinal analysis, hygiene, sanitation, principles and practice of chiropractic and requiring actual attendance of three school years of not less than nine months each, or 3,600 hours of actual class attendance; (2) raises the examination fee to \$25 from \$15, and (3) sets out causes for the revocation, suspension or refusal of licenses.

The new Wyoming law³²⁹ requires applicants for licenses to practice chiropractic to be graduates of recognized schools of chiropractic in which they have actually attended a course of study for at least four years of nine months each, preceded by a four year high school course or its equivalent.

Bills were killed in Illinois,³³⁰ Massachusetts,³³¹ New Jersey,³³² New York³³³ and Pennsylvania³³⁴ to enact separate chiropractic practice acts and create independent chiropractic examining boards.

Unsuccessful attempts were made in six states³³⁵ to amend existing chiropractic practice acts. The Iowa, Nebraska and Rhode Island bills, if enacted, would have extended the scope of a license to practice osteopathy.

An unsuccessful attempt was made in New Jersey³³⁶ to permit a particular chiropractor to be examined in physiotherapy and dietetics and thus to secure a license to practice physiotherapy and dietetics.

An unsuccessful attempt was also made in Washington³³⁷ to create a self-styled "Washington State Chiropractors' Association," which was to operate as an agency of the state and was to be composed of all persons licensed to practice chiropractic in the state. The association apparently was to have the power to fix the qualifications, requirements and procedure for admission to the practice of chiropractic and to establish and enforce rules of professional conduct for its members.

NATUROPATHS.—Amendments to existing naturopathic practice acts were enacted in Connecticut³³⁸ and Utah.³³⁹ The new Connecticut law defines the practice of naturopathy as "the practice of the psychological, mechanical and material sciences of healing as follows: The psychological sciences, such as psychotherapy; the mechanical sciences, such as mechano-therapy, articular manipulation, corrective and orthopedic gymnastics, neuro-therapy, physio-therapy, hydro-therapy, electro-therapy, thermo-therapy, photo-therapy, chromo-therapy, vibro-therapy, concussion and pneumato-therapy, and the material sciences, such as dietetics, and external applications; but shall not mean internal medication or the administering of any substance simulating medicine or the form of medicine, except dehydrated foods."

The new Utah law requires an applicant for a license to practice naturopathy to be a graduate of a legally chartered naturopathic college, in good standing at the time of his graduation, which requires as a prerequisite to graduation at least a four years residence course of instruction over a period of four school years of not less than eight and one-half months of actual school attendance and study in each of such school years, comprising at least 4,500 hours in class work in the subjects required in such school, and in addition such an applicant must be a graduate from a high school requiring an attendance through four school years equal to fifteen units and have completed one year of college work in a college of liberal arts approved by the department of registration. In addition, each applicant must have a course of training of not less than twelve months in a hospital approved by the board of naturopathic physicians or a course of training for a period of twelve months in the office of a licensed naturopath in the state.

Unsuccessful attempts were made in fourteen states³⁴⁰ to enact separate naturopathic practice acts and to create independent boards of naturopathic examiners to examine and license applicants for licenses to practice naturopathy.

Unsuccessful attempts were made to amend the naturopathic practice act of four states.³⁴¹ Bills in three of these states (Florida, Oregon and Utah), if enacted, would have enlarged the scope of a license to practice naturopathy in those states.

An attempt was made again this year in Connecticut,³⁴² which was unsuccessful as in the past, to create certain stated persons a body politic and incorporate by the name of The College of Naturopathic Physicians. The object of the corporation was to be the instruction in the principles, practice and theory of naturopathy and the corporation, it was proposed, was to have the right to establish and maintain hospitals, sanatoriums, infirmaries and clinics and also to award the degree of Doctor of Naturopathy.

An unsuccessful attempt was made so to amend the medical practice act of New Jersey³⁴³ as to authorize the issuance of licenses to naturopaths and to provide that two members of the board of medical examiners be naturopaths.

MASSAGE.—Unsuccessful attempts were made in two states³⁴⁴ to enact separate massage practice acts and to create independent boards to examine and license persons applying for licenses to practice massage.

FAITH HEALERS.—Reference has previously been made on page 885 of the survey concerning legislation enacted and proposed this year relating to faith healers.

SANIPRACTORS.—An unsuccessful attempt was made in Washington³⁴⁵ to enact a separate sanipractic practice act and to establish a sanipractic physicians' examining board, to examine and license persons to practice sanipractic. The bill proposed the following definition for sanipractic: "the science and art of applied prophylactic and therapeutic sanitation, which enables the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises active and passive, manipulation, adjusting tissue, vital organs and anatomical structure by manual, mechanical or electrical instruments or appliances; or other natural agency, to assist nature restore a psychological and physiological interfunction for the purpose of maintaining a normal state of health in mind and body." The bill went on to state that the foregoing definition was copyrighted in 1919 for the purpose of protecting a separate and coordinate principle of healing.

DRUGLESS THERAPY.—NATURAL HEALING ARTS.—Bills proposing to enact separate practice acts for drugless therapists.

drugless practitioners and practitioners of the natural healing arts and to create independent examining and licensing boards were killed in Illinois,³⁴⁶ Indiana³⁴⁷ and Pennsylvania³⁴⁸ respectively.

PHYSIOTHERAPY.—Unsuccessful attempts were made in three states³⁴⁹ to enact a separate physiotherapy practice act and to create an independent board of examiners to examine and license persons desiring to practice physiotherapy. Somewhat similar was the proposal killed in Florida³⁵⁰ to enact a massage practice act and to establish an independent board of examiners to examine and license persons desiring to practice massage, which the bill stated was to be permitted to employ, among other agencies, phytotherapy, dietetics, psychotherapy, suggestotherapy, hydrotherapy, zone therapy, biochemistry, external applications, electrotherapy, mechanotherapy, mechanical and electrical appliances, hygiene, first aid, sanitation, heliotherapy, spinal manipulation and manual bodily manipulation.

An unsuccessful attempt was made in New York³⁵¹ to supplement the medical practice act by enacting a series of provisions with respect to the practice of physiotherapy and to provide a means whereby persons may be licensed to practice physiotherapy.

351. N. Y. S. 965.

PSYCHOLOGISTS.—Bills were killed in Illinois³⁵² and Kansas³⁵³ to enact what in effect were separate psychology practice acts and to create boards of examiners for psychologists. The bills proposed to prohibit any person from practicing as a consulting psychologist without a certificate of registration or a license from the examining board. Apparently no doctor of medicine would have been entitled to receive such a license unless he possessed the degree of doctor of philosophy and psychology or the degree of doctor of science and psychology or the degree of doctor of education or doctor of philosophy and education.

MISCELLANEOUS.—A series of New York bills, all of which were killed,³⁵⁴ proposed to prohibit the practice of roentgenology or radiology except by licensed physicians, osteopaths, dentists or chiropodists, subject, however, to the conditions and limitations of their respective licenses.

A bill was also killed in New York³⁵⁵ which proposed to authorize the board of supervisors in any county to regulate the installation and operation of any machinery, equipment or apparatus to be used for the examination or demonstration of any person or thing by means of fluoroscopic exhibition or shadow imagery registered with photographic materials and the use of roentgen rays.

OFFICIAL NOTES

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Second Annual Meeting, held in Chicago, Jan. 15 and 16, 1940

DR. STANLEY J. SEEGER, Milwaukee, in the Chair

JANUARY 15—MORNING

Report of the Council on Industrial Health

DR. STANLEY J. SEEGER, Milwaukee: The first Congress on Industrial Health, held last year, revealed the complex nature of some of the problems in this field, as well as the vast extent of the field itself. The fact which emerged was one which had previously impressed industrial health workers, namely that conditions of work and their effect on health in relation to every kind of human activity would eventually come into the ambit of medical study and research. At a congress such as this, it is essential to limit our considerations to basic questions which are adaptable to specific application and to authentic reviews having a wide interest to the medical profession. The rapid advance of science has outstripped in many instances the advances of social and professional organization which would make possible the utilization of our knowledge. Controlled experiment is difficult to apply in industry because investigation involves the collection of numerous data on variables which are of value only when collected on a large scale and properly coordinated.

The desirability of a coordination of effort must be apparent even on casual study. While the wider scope of this work may be beyond the realm of medicine and lead into the field of the social sciences, the essential medical character of all industrial health problems and the necessity of medical guidance in their solution should be a focal point in our deliberations. It is necessary that we view in this light the impact of interests whose approach to these problems is from fields other than medicine.

Industrial health is part of the so-called human factor in which so much interest has been displayed in the past thirty years. Early reforms in this field were made on a purely humanitarian basis and not on the basis that industrial output would increase, and health and happiness also. The attitude of industry and industrial techniques have changed. There have developed the speeding up process, the growth of repetitious work at the expense of heavier work, social changes, altered

conditions of work and different types of workers. To date the medical and health functions of the United States have been divided among a multiplicity of departments, bureaus and federal agencies. Since 1875 the American Medical Association has urged the establishment of a single agency in the federal government under which all such functions could be correlated. Such a department would be an effective means of coordinating efforts to improve the health of the industrial worker.

The Council on Industrial Health has been assigned the task of developing an effective program to improve standards of industrial and compensation practice. It has expressed the belief that an important factor in the successful accomplishment of such a program is the development of cooperating agencies in the constituent associations and extension therefrom into the county medical societies. During the past year, committees on industrial health have been organized in most state associations and in several county societies. It is hoped through these agencies to acquaint the Council on Industrial Health with developments in the state and county associations with particular reference to problems of industrial health, and conversely to convey to the committees information about activities and policies of the Council. A means is thus provided also for the interchange of experiences between state committees. Through the agency of these committees, groups interested in industrial health may make a definite impact on the educational programs of their local associations. The excellent program which has been arranged under the auspices of the Chicago Medical Society is a splendid example of the type of educational effort which may be stimulated. Such committees should also define the problems which serve to obstruct the utilization of medical knowledge in the care of the industrial worker. These committees may well concern themselves with the application of the general principles governing the relationships between full-time industrial physicians and the general practitioner.

Vocational Rehabilitation in Relation to Medical Practice and Workmen's Compensation Procedure

MR. TERRY C. FOSTER, Washington, D. C.: Vocational rehabilitation means the rendering of a physically disabled person fit to engage in employment and his placement in employment. It had its origin in the realization on the part of workmen's compensation officials in several of the states that

the payment, to a worker disabled in industry, of compensation for his injury did not solve the problem of getting him back into employment and self support following recovery. By 1918 a number of the states had established vocational rehabilitation divisions as an arm of their workmen's compensation agencies, the purpose being to retain and thus return to employment in new jobs those who through industrial accidents had been deprived of their former jobs.

In 1920 the Congress established a national program to be carried on through the cooperation of the states. This national program is now functioning in forty-seven states, the District of Columbia and the territories of Hawaii and Puerto Rico. Each of these cooperating states and territories maintains a staff of from one to thirty rehabilitation workers whose job it is to find and return disabled persons to employment.

The service operates in about this fashion: When the name of the disabled person is reported or he himself applies to the state rehabilitation service, a case worker is assigned to assist him in working out his problem. The first step taken by the case worker is to secure a rather complete body of information concerning the disabled person and his situation as to (1) his physical condition, (2) his mentality and educational status, (3) his personality—i. e., his ability to get along with others, willingness to work, reliability, and so on, (4) his vocational experience and aptitudes and (5) his life situation—i. e., his family responsibilities, resources and the like. When this information has been collected it is analyzed and a rehabilitation diagnosis is arrived at, an employment objective is selected, and the ways and means of preparing him for and getting the disabled person into the employment selected are worked out with him.

In preparing him for employment, one or more of several services are provided for him, such as physical restoration, an artificial appliance and a special course of vocational training or, in some instances, finding a suitable job may be all that is necessary. But, whatever the services needed, I would emphasize that we stand by him until he is vocationally "well" again or demonstrates that he cannot be made vocationally "well." Naturally we get hold of many cases, just as do you, that cannot be rehabilitated even after our best efforts have been expended and, as do you, we make mistakes. Sometimes you get hold of some of our mistakes, sometimes we get hold of yours, and both of us get hold of the mistakes made by the workmen's compensation commissions.

It is my earnest hope that we can work out a plan by which vocational rehabilitation and workmen's compensation officials and the medical profession can work more closely together in dealing with disabled persons who stand in need of our respective services. Our common job in dealing with persons disabled in industry is to restore such persons to employability and employment. Under this concept it is the job of the medical profession (1) to restore these persons to their maximum physical efficiency, (2) to aid in maintaining their morale by advising them to apply for vocational rehabilitation if they are found to be vocationally handicapped (such advice should be given early in their treatment rather than at the end of it) and (3) to advise with the rehabilitation service and with the compensation officials on the medical aspects of restoring them to employment.

In dealing with certain types of disability, such as tuberculosis, vision, hearing, and cardiac disabilities, the vocational rehabilitation official relies almost entirely on the counsel and advice of the physician in determining the practicability of undertaking the rehabilitation of such cases and in determining the plan by which the individual is to be retained and placed. Likewise, workmen's compensation officials must depend largely on medical advice in the evaluation of the disability and hence the amount of compensation to be paid. I should like to assign to the medical profession a fourth job in dealing with the disabled: that of completing the job of establishing valid and reliable criteria for the evaluation of physical disability. Not only do rehabilitation and compensation officials need such criteria, the courts need it.

Unfortunately the job of the Workmen's Compensation Commission in dealing with persons disabled in industry is too often conceived to be only that of establishing the degree of disability and of paying out the benefits in accordance with

the evaluation. Under the concept which I have stated, their job goes somewhat beyond the simple task of paying out benefits: 1. To see that the disabled person who needs it is given the opportunity of vocational rehabilitation. 2. Within the limits of their discretion, to see that the money paid to the disabled person shall be used as far as practicable in restoring him vocationally and hence to economic self support. In far too many instances, lump sum settlements and commutations are made without any apparent attempt to see that the money paid out will result in his economic reestablishment. 3. To seek, through amendment of those acts needing it, to remove the injustice caused by the so-called second injury clauses. The effect of these clauses in all but a small number of workmen's compensation acts is practically to make it impossible for a disabled person to secure employment in industry.

The job of the vocational rehabilitation service under our conception of joint responsibility for restoring the disabled to vocational competency is outlined as follows: 1. To organize and maintain working relations with them in such way that in every case the combined counsel of the doctor, and the compensation and rehabilitation officials will be brought to bear on the problem of reestablishing the disabled person vocationally, from diagnosis to rehabilitation. 2. To plan and carry out the rehabilitation of the individual on the basis of this combined counsel and understanding rather than on the basis of his own judgment independently arrived at, as is now the case in far too many instances. I have observed over this country thousands of instances in which rehabilitation workers have undertaken the rehabilitation of disabled persons without any attempt to secure medical advice or to utilize the assistance of the workmen's compensation office. Such practice in most instances is inexcusable and frequently results in the futile expenditure of money. 3. To operate the rehabilitation services in such a way that a fair proportion of the number of disabled persons served will be selected from those disabled in industry. The vocational rehabilitation act as originally conceived was intended to cover only those persons disabled in industry. As passed, however, it includes persons disabled from any cause. Unfortunately, in a large number of states, persons disabled in industry are not receiving the consideration contemplated by the sponsors of the legislation. It is high time for industrial surgeons and workmen's compensation officials in such instances to insist that the industrially disabled shall receive an equitable share of service. If our three groups can be brought together and given a common basis of understanding of what we are trying separately to do for the disabled, we should be in better position to coordinate our efforts and thus make fewer mistakes with those cases in which we are all concerned.

To effect this closer working together of the medical profession, workmen's compensation and rehabilitation officials would require joint action by the national organizations of the three groups. This action would probably take the form of the appointment of a representative from each of the three groups. The committee of three thus constituted would draw up a statement of the objectives and a proposed procedure. At the next meeting of each of the organizations the plan could be presented. If approved, the committee would be instructed to proceed to carry the plan into effect. The final form of action would probably be the publication of a joint brochure setting forth what the three groups stand for separately and jointly with regard to standards, procedures and practices in dealing with the disabled. If we believe that the three groups should work more closely together, let's say so and tell the members of our respective groups why and how it can be done. I should like for you to give consideration to my proposal. If you feel inclined to agree with me and wish to do something about it I would welcome the appointment of one of your members or officials to confer with representatives of rehabilitation and workmen's compensation.

DISCUSSION

DR. H. H. KESSLER, Newark, N. J.: The notion was long ago discarded that because a man is suffering from some specific physical defect he is necessarily disabled vocationally. The important thing is to minimize that defect by appropriate treatment. In that respect compensation laws are defective, in that the allowances for medical services are frequently limited so

that ample and adequate treatment is not permissible. In that respect, compensation laws should be adjusted to provide unlimited services, so that the ultimate rehabilitation of the individual is assured. So physical restoration is the fundamental purpose of this whole rehabilitation procedure.

I am sorry that Mr. Foster didn't describe the machinery of the relationship between the federal government organization and the various state agencies. The federal government assists these agencies by providing funds. Each state appropriates a certain amount of money, which is matched by the federal government, and the combined moneys are expended for this total program. There are few states, however, that practice a physical restoration program. New Jersey, fortunately, adopted this procedure from its very beginning and has continued to operate on the philosophy that the first and vital step is physical restoration, and to that end it has created and developed and operated five rehabilitation clinics. These clinics are associated and operated conjointly with the Workmen's Compensation Bureau, so that when individuals are examined for their compensation claims they are automatically referred to the rehabilitation clinic by the state physician who makes the compensation examination. In that way a close cooperation is set up immediately. The individual is referred to the director of the rehabilitation clinic, who makes an appraisal and also decision with respect to the necessity for further treatment, so that the individual gets the benefits of having the maximum amount of physical restoration achieved before any vocational training is instituted, and we find that from 75 to 80 per cent of the individuals who carry through that program require no vocational training. It is a very expensive and unique procedure to take an individual who is over 40 years of age and attempt to train him in a new occupation and change his habits. We have to be very careful in evaluating the mental and physical qualifications of these individuals. The federal government, in defining too rigidly the scope of procedure, also limits the possibilities of rehabilitation in the various state agencies. They could be very much more liberal in providing funds for the physical restoration or at least in matching funds that were provided by the state.

DR. A. S. LEVEN, Chicago: If all the agencies—the medical profession, the rehabilitation agencies, the compensation agencies—were united in doing all they possibly could do to rehabilitate a worker who is permanently disabled, there are still two factors that are a hindrance to this field, namely industry itself and insurance companies. We must educate industry and we must educate insurance companies to this major problem. Industry has not as yet recognized the obligation to the injured workman, and the workmen's compensation laws of the various states are still faulty. If we can combine with the agencies, as Mr. Foster brought out, those two who are mainly concerned from the monetary point of view, then we, as physicians, can go on record to help this cause along.

DR. EARL D. MCBRIDE, Oklahoma City: I think that Mr. Foster has hit a keynote. I would suggest, in order to carry it out efficiently, that the vocational and rehabilitation department in each state have authority to pass on the permanent disability cases in respect to vocation before the settlement is actually made. On account of the system we have, the present commissions are so busy taking care of the cases that come up for adjustment and award that the vocational part is often forgotten. Men may be paid off in lump sums and, as he has suggested, squander their money. The employer, represented in court oftentimes by the attorney of the insurance company, has his own interests to look after. The claimant, perhaps, is anxious to have the award made for his own benefit and thinks little of the future. If there were established in the vocational and rehabilitation department a medical authority who would impartially pass on the prospects of this man who is permanently disabled with regard to his future rehabilitation and employment, and this word could be passed to the bureau or to the commission of the industrial board, then it seems we would get somewhere with respect to the principles Mr. Foster has brought out.

MR. TERRY C. FOSTER, Washington, D. C.: Dr. McBride has hit what I think is the keynote in the whole thing, the bringing of the doctor into the evaluation of the whole program in which the individual is involved. I might say that we are only waiting for the medical profession to complete its job of setting up

criteria for the functional evaluation of the disabled person after maximum correction has been made. I have already worked out with members of the medical profession a series of forms on which the doctor is to record his observations in the examination of disabled persons. As soon as the criteria for the evaluation of disability are completed, I think it won't be difficult to bring the two together, so that the doctor will have greater influence in the final disposition of the cases we serve.

A New Frontier in Medicine

DR. LYDIA G. GIBERSON, New York: Psychiatry, which once was merely custodial in its function, has passed through a difficult therapeutic stage and has reached the full stature of preventive medical technic ready for mass application. When the United States entered the World War, there was brought about the first application of mass psychiatry in world history. For the first time the scientific explorer could see the inception, the progress and the closing phases of a mental ailment, and for the first time he had the authority and the numerical scope with which to control his data and reach reasonably accurate conclusions. The moron and his incidence became nationally known. "Shell shock" and "rehabilitation" became understandable words in the vocabulary of every intelligent American. Many of the tabus surrounding the mentally unfit were shattered and, as a by-product of a social upheaval, psychiatry became therapeutic and not merely custodial.

In the postwar period, psychiatry became, by a series of literary accidents, a most unfortunately popular subject. Under the popular acceptance of Freud, Adler and Jung, mental ills became matters of common conversation. Psychiatry, in this middle period, came closer to being scuttled by popular enthusiasm than it ever had been in the earlier period by lack of opportunity to experiment. This earlier journalistic phase soon settled to the seriously restricted area of the psychiatrist's office. As early as 1916, psychiatrists became aware of the tremendous possibilities inherent in the masses of industrial workers. There was a field in which the conclusions one reached might be put to work to prevent sickness.

In 1917 and 1918 the late Dr. Elmer E. Southard interested the Engineering Foundation in the possibilities of a psychiatric approach to industrial personnel problems. In a survey in 1920 he found that 62 per cent of more than 4,000 cases observed reached the discharge status through traits of social incompetence rather than occupational incompetence. In 1922 the Metropolitan Life Insurance Company started a full psychiatric service for their employees, a service which continues to the present day. Later, in 1924, Macy's Department Store in New York, employing about 9,000 persons, began a psychiatric investigation which today serves as a research department.

The next major impetus came from industrial personnel groups in 1932 when they began to apply psychologic concepts to their perennial problems of labor turnover and labor placement. Safety workers and other industrial control groups have altered their procedures to allow for psychiatric techniques. The progress from 1934 to 1940 has been a slow one of group education. Thus psychiatry has moved slowly away from the fashionable patient who alone could afford a two year treatment for real or fancied mental ailments. Slowly the mists created by novelty and jargon have lifted. The medical facts have emerged. Psychiatry can now open its new development in a great industrial laboratory where, by honestly sympathetic application of its principles, mental sickness may be not merely detected but prevented.

Workers are torn by two, often opposed, social systems; in his home and in his church he is a part of the century old compulsions which demand a unity of attitude if he is to attain happiness; in his factory he is in another world curiously inadequate and incomplete. Monotony produces the accident-prone and the maladjusted worker. Mental factors account for some 85 to 90 per cent of industrial accidents. Personnel workers have been investigating with the aid of psychiatrists the emotional causes of absenteeism and of friction among their employees. Industrial relations experts have been concerning themselves with the psychology of conflict in their attempts to get at the sources of trouble before it mushrooms into ugly proportions. Social workers have found that many of the complaints they hear are based on emotional rather than physical environments.

DISCUSSION

DR. CLARENCE D. SELBY, Detroit: Despite the fact that the industrial surgeon of thirty years ago has evolved into other specialties, such as industrial medicine, industrial hygiene and now preventive medicine, there is need for further evolution. The industrial physician today must become to some degree a psychologist, and you can readily understand why. Industrial physicians speak rather glibly of safe placement of employees or suitable placement in occupation and make a rather complete physical examination, but we do not examine the man himself. May we consider for the moment man as an automatic machine? But we, by the same token, completely ignore the mind of the man who is back of that machine. I recognize that the industrial physician has no responsibility toward the disordered mind unless that disorder results from occupation. The treatment of cases of that nature are the right and purpose and the obligation of the general practitioner. The physician in industry has no intention or right of depriving him of that privilege. Nevertheless there is a constant stream of employees flowing through the medical service, usually equivalent to the number of employees on the payroll each month, who have stories to tell to the physician. They may be expressions of a purely normal individual, or expressions of a disordered mind. So far as the physician in industry is concerned, it seems to me they are largely expressions of worry, and Dr. Giberson has brought that out in her paper. The men out in the plant just naturally gravitate into the medical office for the purpose of telling something which has no relationship to employment and is of a purely personal nature, but they must tell somebody and they look on the doctor as the one to whom they can tell that. If the medical profession can utilize that tendency of the worker to relieve these sources of worry by psychologic methods, if you please, the industrial physician will be in a vastly superior position with respect to his ability to serve the employee group. That might be classified as counsel or service. I am completely at a loss to know just how to evaluate these worries that come across the desk to me. I should like to have the psychologist put down a series of rules that would tell me how to proceed, something practical that will permit us to render the service that we wish to render but do not know how to do. There is another phase to psychology in industry that is very important but at the moment I believe beyond our ability even to comprehend, and that is what might be called man evaluation at the time of employment. We are able to examine the workman physically but we haven't the slightest conception of what we should do to find out what type of work the individuals are mentally fitted for. There are many examples. How the doctor can codify those and classify them, put them into categories so he can specify on the report which he sends to the employment department that this man is or is not mentally suited to this job is what we need of the psychiatrist.

DR. L. D. BRISTOL, New York: I should like to emphasize one phase of this subject in developing the discussion of Dr. Giberson's paper, and that is not only our responsibility as industrial physicians with reference to these problems as they pertain to the employer but our responsibility in educating management itself to the place of mental hygiene and the use of at least part time psychiatrists in the industrial health program. The average representative of management thinks in terms of custodial care and actual cases of mental disease, and that the psychiatrist is only interested in that aspect of the problem. He has shied away somewhat, as the executive, from this whole subject of mental health and the services of the psychiatrist. We must emphasize to management how the physician specializing in this field can be of assistance to him. I had the privilege of attending the Personnel Section of the American Management Association. What were they talking about? They were discussing What is the employee thinking about? What is he worrying about? What can we do to help him be satisfied with his job? We as industrial physicians should bring to the attention of the personnel director the fact that bad employee relations are very largely a matter of bad mental hygiene and that perhaps if he will avail himself of the services of not only his own physician in his organization but possibly the part time services of a psychiatrist he can do much to prevent these conditions he is talking so seriously about in his personnel meetings.

DR. LYDIA G. GIBERSON, New York: Dr. Selby has probably given you a much better psychiatric approach than any psychiatrist could, because he has been, for many years, practicing what I am trying to preach. I should like to tell Dr. Bristol, in all fairness to industry, that I believe management itself is headed for the doctors. Since 1938 I have had personally twenty inquiries from management groups to one from a medical group. I should like to mention the American Management Association. I think it was in 1926 that I was the guest speaker at the American Management luncheon, and for that one luncheon the personnel management group chose the subject of psychiatry. In Chicago on November 30 the Industrial Relations Association also had this subject featured. So I believe it is up to us as doctors to go out and do something about this. In closing, I would like to emphasize that before you can be a good psychiatrist you must first be a good doctor.

Adequate Nutrition for the Industrial Worker

LELA E. BOOHER, PH.D., Washington, D. C.: This paper was published in full in THE JOURNAL, February 17, page 548.

DISCUSSION

DR. MORRIS FISHBURN, Chicago: I have been asked to discuss this paper probably because I am Chairman of the Council on Foods of the American Medical Association. The Council on Foods has been greatly concerned about practically every aspect of the subject as Dr. Booher presented it to you. I have recently reviewed a book published by the Department of Agriculture called "Food and Life." I suppose in that book we have more information about food and its distribution and the needs of humanity in the United States than is probably available anywhere else. The main problem, as I see it, in applying this material to the worker in industry is that workers in the United States are scattered through forty-eight different states and innumerable cities and villages and under all sorts of social and economic conditions. They are not easy to educate in the matter of food and not easy to educate with scientific material given away by the government and by educators. At the same time, commercial agencies of one type or another are endeavoring to educate them at considerable expense and have much more influence and much more experience in education than the scientists have generally. The material you hear over the radio as to what you can buy for a certain amount of money and what you ought to eat is what really educates the children of the United States and the workers regarding diet. In analyzing the statistics regarding the extra feedings of the worker in industry, I have always been concerned with the fact that the worker in industry has as many different considerations disturbing him as the person who is buying food for the home. Sometimes we forget that fifteen minute rest periods at two hour intervals will also enable him to turn out more work and probably better work than an extra glass of milk every two hours. Sometimes we forget that, if you give him a little more light to work with, and better light, he will suddenly start turning out more work. Sometimes changing the ventilation, the chair on which he sits, and all sorts of changes affect every one of these experiments. I suppose it is up to the industrial physician to work out a suitable program for testing the relationship of diet to the worker's output and to his general health. A single important observation of the type of that having to do with sodium chloride intake for the worker under conditions of excessive heat is worth any amount of effort that the industrial physician or any one else may care to put on an experiment of that sort. Dr. Booher has given a fine statement of standards and of the present status of knowledge on the relationship of nutrition to industry. It might be well if the Council on Industrial Health could take up the question of how to get management and the workers themselves to pay more attention to the knowledge we now have. It is primarily an economic problem for workers in the low income levels. For workers in the higher income levels it is a problem of education. American workers spend for themselves and their families about 30 per cent of their income on food. With 30 per cent of their income they ought to be able to get a fairly good standard of nutrition. The translation of what we know, for the worker, into a language he can understand is also exceedingly important. All together, we have a great problem in how

to control advertising of food products, which the Council on Foods is endeavoring to do and, second, to get knowledge over to the worker in a language he can understand.

DR. L. D. BRISTOL, New York: I should like to indicate something with reference to the practical application of a nutrition program in industry. First of all, it should be the function of the industrial physician to keep these facts of malnutrition and adequate nutrition in mind in dealing with the individual employees. Some companies see fit to go into the question of extra feedings. Other companies have preferred to emphasize the educational aspects of this whole problem. During the last ten years, as a follow-up to our regular health course, for women particularly, we have been carrying on a so-called nutrition course under the guidance of a trained nutritionist. We have already had something like 10,000 women employees who have been graduated from a ten lesson nutrition course, a purely voluntary course given on the employees' own time, with trained instructors and the necessary textbooks. While as yet we haven't been able to measure results from the standpoint of efficiency or decreased amount of sickness or improved positive health, we have definitely been able to measure the improvement in the choice and selection on the part of employees when it comes to their food, particularly in our cafeteria. In all of our companies, all of our offices have a lunchroom or cafeteria, and it is possible for us to judge the demand on the part of employees for certain articles of food. Previous to this health course we know that, particularly during rest periods, the employee would go to a counter and get some chocolate candy and a soft drink. We have been able to determine that as a result of this nutrition course for employees a great increase has taken place in the demand for milk and green, leafy vegetables. That is one way of measuring nutrition education. The very fact that they are selecting a better type of food is a positive way of getting at this subject. I am not so much in favor of management trying to add extra feedings. I think that, if anything, we should educate the employees to do this thing from their own standpoint and see that they get three better meals a day. We found that among our employees breakfast is nothing but a sip and run meal, if you will, a hurried cup of coffee grabbed on the way to the office. We know that lunch is frequently nothing but a very poor sandwich and a cup of tea. So much of our educational work for employees involves three satisfactory meals a day, with the hope that the employee will take these things to heart and that, in the long run, it must improve his health.

DR. LELA E. BOOHER, Washington, D. C.: Something Dr. Fishbein mentioned makes me a little worried about those tables I gave you. I hope you are going to keep those in your office and use them as your source of knowledge, to communicate and translate to the worker. It makes a chill run down my spine when I think it might be handed to industrial workers who would be confused about it all. Certainly, teaspoons and bottles of things are what the average person thinks about when he thinks of quantities. We answer about fifty letters on foods and nutrition a day, and the questions are amazing. They want the government to cure every disease they can possibly think of. Diets for different diseases are thrown in at us, until we have worked out a form letter in which we just change the name of the disease they have asked about and refer them to their physician. It isn't possible to give help *en masse*. That individual problem is there in nutrition, as it still is in medicine.

JANUARY 15—AFTERNOON

DR. WARREN E. DRAVER, Washington, D. C., in the Chair

SYPHILIS IN INDUSTRY

Syphilis in Industry, with Special Reference to Its Incidence and Relation to Trauma

DRS. EARL D. OSBORNE, HERBERT L. TRAENKLE and FRANK A. DOLCE, Buffalo: The importance of syphilis in industry was recognized long before there was any thought of the present campaign against syphilis. Studies on isolated industries, such as Stokes and Brehmer's on railroad workers in 1920, had awakened the realization in the minds of executives of some corporations to the responsibilities of management in the control of syphilis. It was only natural, therefore, that in the public health campaign against syphilis, begun in 1935, organized industry should present a fertile field for an intelligent attack.

Stokes, Beerman and Ingraham have recently summarized the various studies on the incidence of syphilis in industry from 1920 to date. When the campaign against syphilis was instituted in Buffalo, in August 1935, it was apparent that in any approach to the problem of syphilis in industry in a large industrial city, a determination of the incidence of the disease in industry generally was absolutely essential. With this in mind, the director of syphilis control of Buffalo began a survey of all blood serologic tests performed in the laboratory of the department of health of Buffalo from the industrial concerns throughout the city.

During the first two and one half years of the survey, Jan. 1, 1935, to July 1, 1937, males in general industry showed 6.7 per cent positive tests and females 5.9 per cent, or a combined percentage of 6.6. During this same period there were 6.1 per cent positive tests in food handlers and 4.6 per cent positive tests among patients seen by private physicians. During the last six months of 1937 and the entire year of 1938, 2,500 additional routine serologic tests were performed on the bloods of industrial employees. Probably as a result of the intensive campaign against syphilis, the percentage of positive tests dropped to an even 5. If from these figures the tests performed on Negroes are subtracted, the final result is approximately 5 per cent positive during the initial period of 1935 and 1936 and the first half of 1937, and 4 per cent during the second period. In 1938 the number of early or new cases of syphilis in the entire city dropped to approximately one third the number reported in 1935.

An industry that employs a large percentage of individuals in the age group from 18 to 30 may expect a relatively high incidence of early syphilis. An organization that employs a large percentage of individuals in the age group from 30 to 40 may expect relatively few cases of early syphilis and a high preponderance of latent syphilis and early cardiovascular and neurosyphilis. An industry with many employees of long duration in the age group over 40 may expect a high incidence of late cardiovascular and neurosyphilis. It is important for industrial physicians to know and appreciate which type of late syphilis may be expected to affect operating efficiency and to present the greatest hazard from the standpoint of injury to the employee and the public.

With these points in mind, it was advantageous to survey a large group of industrial workers examined at the Edward J. Meyer Memorial Hospital. Four thousand and six individuals were examined. As the patients of this hospital are mostly unemployed or in the lowest income group, it was desirable to survey a similar group of industrial workers seen in private practice who also had syphilis and had received a thorough physical and serologic study. Of 399 workers in the "heavy" industries, with syphilis, less than 7 per cent presented early syphilis. Among the workers in the "light" industry group, the percentage of early syphilis was 23.8. The discrepancy emphasizes the necessity for periodic examinations and serologic tests on the workers in the so-called light industries. In the heavy industry group 18.5 per cent showed evidences of neurosyphilis and 29.9 per cent of the workers in the light industry group were found to have neurosyphilis. Clerks, skilled workers and railroad employees with asymptomatic and late neurosyphilis can account for a large amount of lowered operating efficiency, direct monetary losses and accidents involving the public, the fellow workers and themselves. In the heavy industry group 13.5 per cent showed evidences of cardiovascular syphilis, whereas in the light industry group, in which physical stress is reduced to a minimum, only 5 per cent showed evidences of cardiovascular syphilis. Our observations on patients developing aneurysms and aortic regurgitation as a result of trauma or severe exertion while employed in heavy industries indicate that each case costs the industry some five to ten thousand dollars. The detection of syphilis in heavy industries, where it is largely neglected, is therefore of definite practical economic value to the industry itself as well as to the employee. In the combined groups of the food handlers, seventy-seven had syphilis and thirteen had manifestations of early or infectious syphilis. If it is desirable to detect early infectious cases among food handlers more than it is among other groups, and we doubt that it is, a routine serologic test, performed every three to six months, cannot be expected to pick up more than 25 to 50 per cent of the infectious cases during the first week

of their existence. If compulsory serologic tests are performed on food handlers with the idea of protecting the public from infection, we believe that the entire plan is wasted effort. We have never seen a case of syphilis transmitted by food handlers or, for that matter, by clerks or barbers meeting the public, through intermediate contact with plates, glasses, cups, vegetables or fruits. The greatest danger from these individuals is the transference of the disease to other employees and to patrons of the establishment through the usual method of sexual intercourse. It would be more to the public's benefit to have laws requiring the compulsory physical and serologic examination of employees of all public transportation companies.

We have reviewed our cases of syphilis complicating trauma. These cases are listed under the following diagnoses: (1) surgical incision in preexisting periosteal gumma; (2) nodulo-ulcerative tertiary syphilis occurring at site of recent injury; (3) fracture at site of preexisting osseous gummas; (4) periosteal gumma following a blow on the tibia; (5) osseous gummas of the skull following a blow on the top of the head from a timber; (6) interstitial keratitis following an injury to the cornea from a foreign body in congenital syphilis; (7) interstitial keratitis after a burn of the cornea from hot solder in acquired syphilis; (8) dementia paralytica following a severe head injury; (9) dementia paralytica following prolonged surgical anesthesia; (10) dementia paralytica following high temperature from streptococcal infection; (11) aortic aneurysm following heavy physical exertion.

In analyzing these cases, the following conclusions were apparent. 1. The average cost of each case to the industry was exceedingly high. 2. The proper syphilis program in each industry involved would have prevented syphilis from being a factor in any case. 3. No cases of syphilis complicating trauma have been seen by us in plants having an adequate syphilis program.

We submit the following suggestions regarding a syphilis program in industry:

1. Establish routine preemployment physical and serologic examinations and periodic reexaminations of all employees. This should include executives, clerks and skilled workers as well as the purely physical workers.

2. Sponsor refresher or postgraduate courses in syphilology for members of the medical staff and make adequate consultation and supervisory services available.

3. Become acquainted with the following scientific facts: (a) the danger of transmitting syphilis in industry from direct or indirect contact (tools, drinking cups, door knobs, toilet seats) is absolutely minimal and the factor of least importance in the control of syphilis in industry. (b) The positive serologic test is no criterion of infectiousness and should be interpreted only by a physician on the basis of a complete physical examination and determination of type or kind of syphilis present. (c) The positive serologic test or its degree of positiveness is no measurement of the stage or seriousness of the disease or effectiveness of treatment. (d) The negative serologic test without physical examination is open to the same criticism as is the positive test. The highly infectious primary lesion is not accompanied by a positive blood test during the first four to ten days of its existence and an appreciable percentage of individuals (5 to 10, depending on the laboratory technique) with late syphilis have negative blood tests. This fact together with the necessity for discovering newly acquired infections among old employees is the reason for periodic reexaminations.

4. Based on a knowledge of the foregoing facts, an enlightened policy toward prospective and old employees should include: (a) Rejection only of those syphilitic employees who show evidences of damaging late syphilis or early infectious syphilis. (b) Insistence on complete physical examination, including spinal fluid examination for all employees found to have syphilis. (c) Insistence on adequate modern treatment with supervision by a syphilologist if indicated in special cases. (d) Transfer of employees with cardiovascular and neurosyphilis to positions entailing no hazards for themselves, their co-workers or the public. (e) Dismissal only of those syphilitic employees who refuse to cooperate. There is nothing more unjust than the blind dismissal of an employee because of a positive Wassermann reaction. With cooperation and proper treatment, the industry will gain a loyal employee and take on

no increased hazard. (f) Maintenance of strict confidential relationship between employee and company physician. (g) Cooperation with local health authorities in reporting and tracing the shifting or migrating worker with syphilis.

For industrial physicians and surgeons:

1. Become conversant with published data regarding the direct and indirect cost of syphilis to industry in general and your own plant in particular. Use this knowledge in "selling" your company executives on a proper modern syphilis program.

2. Improve your own knowledge about syphilis with postgraduate courses and secure adequate expert advice and guidance from a qualified syphilologist.

3. Cooperate with the local public health authorities in tracing "contacts" and itinerant workers with syphilis, and also in the elimination of houses of prostitution from the neighborhood of the plant.

4. Keep a complete record of the physical examination and treatment of every syphilitic employee. Check his treatment with the recognized published systems of treatment indicated in his case (early, latent, liver, cardiovascular, skin, bone, special sense organ and neurosyphilis). Insist on consultation with specialist where indicated so as to check up on the adequacy of treatment.

5. Don't be satisfied with a diagnosis of syphilis. Insist on knowing the kind or type of syphilis and the degree of damage, if possible, in the principal organs involved.

6. Remember that late cardiovascular syphilis is from two to three times as common in workers doing heavy physical labor as in those performing jobs requiring little or no physical strain. Remember also that neurosyphilis is almost twice as common in executives, clerks and skilled workers as in "heavy" laborers.

7. Remember that all persons with syphilis, unless it is contraindicated by old age or general debility, should have a spinal fluid examination. Approximately 15 per cent of the workers with "latent" syphilis will be found to have a positive spinal fluid.

8. Remember that persons with cardiovascular and neurosyphilis require specialized treatment from the beginning.

Syphilis Case Finding in Industry

DR. ALBERT E. RUSSELL, Chicago: This article will be published in full in THE JOURNAL.

Integrating Syphilis Control Between the Industrial and the Private Practitioner

DR. HAROLD A. VONACHEN, Peoria, Ill.: With the acceptance of a syphilis control program by industrial organizations, the medical divisions assume responsibilities which require conscientious administration of a very definite routine. The various plans of syphilis control programs differ little in the main, with slight variant in detail. The most perplexing problem seems to be the method of approach to the family physician. The relationship between the family physician and the industrial physician must be based on honesty of purpose always in the light of past experiences. The industrial physician needs the aid of the family physician in his care of compensation cases, while the family physician requires the good will of the industries medical division in the reference of non-occupational cases. The family physician must be convinced that never will the medical division of industry render treatment in cases of syphilis. When a worker is informed of his syphilitic condition, he is in need of a friend to give him advice and guidance. If the procedure is attempted by the private physician alone, the employee is likely to think that, because the treatment is long and expensive, he is being over-treated. The plant physician can and does advise the employee that the treatment of syphilis requires time and money and that the family physician must follow the long continuous course of treatment.

In our present plan of syphilis control, the individual, following an interview with the personnel and employment departments, goes to the medical department for physical examination. If the Kahn test is found positive, the employee is given a personal interview with either the medical director or the plant physician and is informed that the blood test reveals evidence of syphilis and that he must present himself to his family physician for a check of his Kahn test. The employee is given ten days to return and, if the results of the blood test taken by

the family physician fail to agree with the primary test, a specimen is sent to a third and a fourth laboratory. If the blood tests check, the employee is told that the information is absolutely confidential between himself, the industrial physician and the family physician and that absolutely no information has been given to the employment or personnel departments. This is essential, as on it depends the success or failure of the plan.

The employee is then told that he must present himself to his family physician for treatment and that he will be given employment as long as he continues to cooperate. Each month thereafter the employee must present to the medical division a slip signed by the family physician that treatment has been received. A careful check and file is kept so that automatically the medical division knows each person that is expected on the given date to present his slip. If reports from the family practitioner are favorable, the employee continues employment. If not, he is called to the medical division to ascertain the reasons for his neglect and further advice is given and warning as to the necessity of treatment. Continuous neglect calls for dismissal of the employee.

After seventy weeks the family physician is consulted as to the amount of treatment received by the patient. If it is considered adequate he is requested to return every six months for reexamination.

The operation of this plan depends on the type of syphilis that presents itself in the individual. Employees in the primary or secondary stages, of course, are rejected, and also those who have definite evidence of neurosyphilis. There can be no objection to this plan by the family physician, as the cases are referred directly to him for treatment and the only requisite is cooperation in maintaining the treatment for the proper period of time, and he receives only those who are capable of paying, as the others are referred to the state clinics, who are asked to follow the same procedure.

I believe that the industrial practitioner might and should inform the employee of the need of protection and investigation of his family, but certainly the duty of reporting to the state, and the family diagnosis, belong strictly to the family physician.

In my opinion there should be greater unity in fees and a budgeting of the individual's earnings to cover adequately the payments of his treatment. The fact that an individual is given employment with the understanding that treatment is necessary should guarantee the treating physician his fees. The details of a syphilis control program are unimportant if it provides adequate treatment and allows the employee to continue his God-given right to earn a living for himself and his dependents.

Syphilis and Employment

DR. HARVEY BARTLE, Philadelphia: Our sympathy is aroused for afflicted persons and it becomes the primary motivating factor in rendering all possible assistance to restore health to these unfortunates. The humane reaction is the dominant factor in the restoration of optimism, health and happiness to these persons. In major industries there is a familial relationship between employer and employee; consequently industry becomes morally obligated if not otherwise to the workers. It is not simply a moral right to relegate to the state as a charge or beneficiary known infected persons. There are other avenues open for successful rehabilitation, preferably accomplished through the maintenance of earning power. To do otherwise would in many instances produce a disgruntled citizen.

Social and economic factors of employment lead to the impression that industry has an obligation to society in not refusing employment to any one without good and sufficient reasons, thus creating unwarrantedly a group of unemployed and unemployable persons. The present day emphasis on social security in its blanket approach surely will not condone the exclusion of any group indiscriminately when there is a way out, reasonable and fair, and with a minimum of industrial risk if properly supervised. This responsibility is difficult to evaluate in the case of the syphilitic because of the varying physical and mental impedimenta. Every trained artisan is a capital investment and any personal handicap is disturbing for many reasons.

What advice is it possible to give to industrial management about the advisability of arbitrarily refusing employment to all known syphilitic applicants? The well informed physician in

industry can allay any perturbation about the transmissibility of the disease in the industrial environment. He cannot be quite so reassuring about the purely economic considerations which have to do with slowing up production, absenteeism, proneness to accident, and neurologic and mental changes with their consequences. Industry has little evidence on which to base a policy of discrimination against applicants who are known to have syphilis or the dismissal from service of persons who acquire syphilis after employment. Do not misunderstand this pronouncement. There must be some protection to the employer as well as to the employee. The modifying factor is the status of the disease.

Syphilis of the central nervous system is a real industrial medical problem. Persons in this category who sustain slight trauma may have more serious aspects of the disease precipitated. From the neurologic angle are frequently seen tremors, changes in sensation, disturbance of locomotion and incoordination, which are obviously handicaps of varying degree. If persons with these manifestations are retained in the service, special placement and supervision are certainly needed to protect the individual and as a general safety measure. Pathologic structural changes in heart and blood vessels are susceptible of various interpretation. They are admittedly fraught with potential danger from the standpoint of sudden incapacity. The manifestations of the disease are the criteria on which the disposition of the afflicted persons on an employment status must be predicated.

What then is the advisable thing to do from a medical point of view? The following postulates may appropriately express the present generally accepted opinions operative as a guide in personnel planning by industry:

1. A person having had an initial lesion or congenital syphilis, with or without a positive blood Wassermann reaction, may be accepted as a new employee.

2. A person with an open lesion should not be accepted.

3. A person with a positive blood Wassermann reaction and not under proper, safe and adequate treatment should not be accepted unless it has been definitely established that the individual is Wassermann fast.

4. Those having pathologic changes of the heart and vascular system of a precarious nature should not be accepted or permitted to work, even if the person should be under medical supervision.

5. Persons with advanced pathologic changes in the bony structures are a menace in any work and should be guardedly employed.

6. Those having pathologic changes in the brain and spinal cord should not be accepted and those in active service should be relegated to placements of safety with periodic examinations.

DISCUSSION ON SYPHILIS IN INDUSTRY

DR. HUNTINGTON WILLIAMS, Baltimore: There will be little disagreement with Dr. Osborne and his co-workers on the matter of the lack of necessity for syphilis tests for milk and food handlers and other special groups. It is often the duty of the medical director in industry to try to persuade the head of the industry that that is so. Drs. Osborne, Traenkle and Dolce hit a keynote in the emphasis we must all put on the terrific cost of syphilis in and out of industry. The geographic location in the country has a big effect on the amount of syphilis present in the community. Dr. Russell gave us some statistics. Magnificent work has been done in Scandinavia, but I am a little leery of statistics. Sir Arthur Newson told us that when dealing with statistics you should treat them like sausages: who made them, out of what they were made, and for what purposes they were made. When I prepared the first paper I ever gave on a health topic I went to the director of statistics in the state health department in Albany and asked him for some figures on tuberculosis. He said "Doctor, what side of the argument are you on? If you are against it, I will take it out of this pigeonhole, but if you are for it I will take it out of this pigeonhole." Dr. Vonachen and I agree that syphilis records ought to be confidential. What is confidential? It is confidential between three or four people. Why not add a fifth? I would, as a health officer, disagree with him when he says that the industrial director should not report to the health department. In most states

that would be illegal. I agree with practically everything Dr. Bartle said. Dr. Osborne and his co-authors apparently wrote their paper in part around the same editorial by Moore, which is the basis of the plan which we have put to work on syphilis control in Baltimore. I am sure that Dr. Vonachen visualized both the industrial and the private practitioner as part of a larger medical team which includes every physician within a community under a civic and perhaps even a health department banner; a team whose goal is the control of syphilis through a more effective and community-wide application of diagnosis, therapeutics and epidemiology. I believe that case finding in syphilis requires a different technic from that used for most other communicable diseases, and particularly tuberculosis. The epidemiologist in syphilis must work hand in hand with carefully trained social workers in the clinics, and many industrial and family physicians must broaden their vision of community responsibility if syphilis is going to be fought down. Reliable figures on the prevalence of syphilis are difficult to get. Month after month statistics pile up in health departments on reported cases of syphilis, but many of the reports represent old cases that may have been reported at some other time, under some other name or in some other health jurisdiction. There are many duplicates in the reports that go to make 760 times as much syphilis in America as in Sweden. A plan which, during the past three years, has been developed in our city for syphilis control in industry was described in the July 1938 issue of *Baltimore Health News*. It is based primarily on a very striking editorial in the May 1937 issue of the *American Journal of Syphilis, Gonorrhea and Venereal Diseases* and simultaneously in the *Journal of Industrial Hygiene and Toxicology*. The plan emphasizes the truth that the public often seems loath to accept the fact that syphilis spreads relatively rarely except by the sexual route. It also stresses the fact that a positive blood test does not always mean communicable syphilis. The heart of the Baltimore Plan is a written agreement entered into voluntarily by the medical director representing any industrial organization in which application is made for the health department laboratory blood testing of employees and which provides for the reporting and follow-up of positive cases but which includes the very special stipulation that "No discrimination is to be practiced on employees or prospective employees because they show evidence of venereal disease on laboratory tests but are otherwise physically fit for the employment which they have or seek." That is the kernel of the whole plan. It is taken right out of Dr. Moore's editorial. From February 1938 to date, eight industrial organizations in Baltimore employing, roughly, 8,490 workers, through their medical directors, have entered into what I consider may prove to be a most satisfactory community approach to the control of syphilis in industry. In Baltimore we use the serodiagnostic test. We have thrown the word "Wassermann" overboard because we don't use the test any more. If we can get the public to throw the term "Wassermann" overboard I think we would be better off, because usually they misspell it anyway. The Baltimore City Health Department has cooperated with various industrial organizations in our city along educational lines by providing moving pictures, speakers, exhibits and press and radio material on syphilis control in industry. Our particular plan may offer a reasonable and carefully guarded approach to the big problem ahead. It may need modification in some community other than ours. We have found ourselves blocked in a large inter-city industry because the city health department in their home office city makes a practice of taking the blood samples of the industrial employees without cost to the industry. We can't afford to do that. The home office of this industry issued orders that their medical director in Baltimore might not cooperate with our plan, which requires the industrial physician to take his own blood specimens and submit them to our health department laboratory. We shall find an answer on that. Occasionally we find that large interstate industrial units are hard to budge when, on the advice of their medical directors, they positively insist on a policy of discharging employees in certain categories merely on the basis of a positive blood test when the employee is known to be otherwise physically fit for his job. Careless or unthinking members

of the medical profession may also disrupt a smooth working syphilis control program and the equanimity of the occasional medical director in industry. I have a few copies of the written outline of the plan available for you, if you should like to take them with you.

DR. CHRISTOPHER LEGGO, Crockett, Calif.: I speak as a plant physician with regard to adequate propaganda, which adequate propaganda means not too much and not too little. Where a program is in force, where the syphilitic are all known and are handled personally, I feel that the less propaganda, the fewer posters, the less that is brought in, the better. If in a situation such as the fourth speaker describes where Wassermann tests are not routine, I think propaganda might be in order to encourage people to come for investigation. Syphilis can be cured. Syphilophobia can't be cured, and those people suffer more and are more inadequate than the actually diseased persons. The propaganda, if it is directed by a conservative plant physician in whom the person has confidence and is put out by him personally, will attract the attention of the introspective introvert, but the extrovert whom you want to change throws it away and pays no attention.

DR. BEVERLY L. VOSBURGH, Schenectady, N. Y.: In 1932 we started a program of routine Wassermann tests and found at that time about 4.4 per cent incidence. That incidence has gradually decreased until in 1939 it was 1.8 per cent. We pay the local laboratory \$1,000 a year for doing our Wassermann tests. We have to convince the management occasionally that that \$1,000 is a worthwhile investment. We find not infrequently that patients who have repeated positive Wassermann reactions have no knowledge of syphilis whatever. They haven't the slightest idea how they contracted it. It is hard to convince those people that the presence of repeated positive Wassermann reactions is adequate excuse for two years of uninterrupted treatment. The cost of treatment for the patient in our community is about \$5 per treatment a week. Over a period of two years that means roughly \$500, which is quite an item to a man who makes perhaps \$20 to \$25 a week. Some of those people migrate to clinics where they have a pay scale commensurate with their incomes. There are many people in industry who say they do not have a family physician. They don't want to go to clinics, and it is a bit difficult to pick out a physician for treatment. It took us a long time to formulate a policy in respect to syphilis. At first, in 1932, practically all of the people we were examining or reexamining were old timers. We had no difficulty in placing them at work. Even the neurosyphilitic and those affected with cardiovascular lesions were usually safely placed. When it comes to the present time, many of the people we find with syphilis are new employees who have no service. When it comes to the policy in regard to new employees, it is a little different.

MR. VERNE A. ZIMMER, Washington, D. C.: I do not represent labor but in my official capacity I have talked to many labor leaders about this program. I find them sympathetic with this movement to check syphilis but distinctly unsympathetic toward the idea of picking the industrial worker, out of all the groups, as the guinea pig. In a conversation one of the labor leaders of fairly broad national reputation in Washington said "Labor would feel better about this move to examine for syphilis all workers in industry if some other groups would step forward first as an example. Why pick on the worker more than the medical profession? Why pick on the worker more than the chamber of commerce? Why not pick out the church congregations? They are accessible as groups." Labor doesn't believe you can put up a program in industry for preemployment physical examinations for syphilis that doesn't involve general conditions as well. In the main, labor doesn't like the preemployment physical examinations, because it has had bad experience with it. I was interested to hear Dr. Russell mention that point. He said that unfortunately there are employers who immediately discharge or who refuse to hire the man with a plus Wassermann reaction. I have been interested in one item this afternoon, and that is the debunking of the idea that these spirochetes are hopping around and you can get them anywhere, even in the dining room. Labor will be pleased to know that, while it is theoretically possible, it doesn't really happen. Labor would have been interested to hear these com-

ments on cost today. There are several million workers in the United States not averaging \$1,000 a year. How is one of these going to take even \$100 and divert it from his family for treatment for himself? If you are going to emphasize this program with respect to the lower wage groups, there must be more monetary aid from the national, state or local governments. I am secretary of the International Association of Accident Boards and Commissions. In the years in which I was engaged in the actual administration of workmen's compensation, this subject was an old one. I have listened to one speaker after another this afternoon point out that in this program the employers can save lots of money, heavy losses, by watching for syphilis and perhaps eliminating the syphilitic. I probably have seen many reports on injured workers. In the aggregate I have seen quite a large number of cases in which underlying syphilis contributed tremendously to the cost, but out of an average of 100,000 cases a year in my jurisdiction a very small percentage of the total were in any way influenced by the syphilitic condition. It should be remembered that, under the principles of workmen's compensation, no employer, unless he is self insured, bears directly the cost of one injury. It is spread over industry in general. He pays in proportion to the experience in his particular group. That is the proper principle. Otherwise there would be even more restrictive physical examinations than exist today.

DR. A. S. LEVEN, Chicago: The reason I pop up at these meetings is that I feel the rank and file doctor ought to get up and say something. To leave everything to the authors of papers is all right—we can read it in our journals; but I think if popular discussion arises on the floor, then we really get an expression of opinion. I should like to suggest that more get up to speak if time permits. Every author has told us definitely the etiology, the symptomatology and the treatment for syphilis, both in industry and out of industry. Yet with all this information there are still the problems of syphilis. The reason is that the real etiologic factor, which was pointed out by the last discussor, is the socio-economic factor. We talk about that point but we ought to reemphasize it time and time again. In the problems of social diseases, tuberculosis and syphilis, when our society learns to cure our social and our economic ills we shall cure syphilis and tuberculosis.

DR. NORBERT ENZER, Milwaukee: In 1927 a routine Wassermann test was instituted for all patients admitted to our hospital and later this was amplified by other serologic tests on syphilis. I am unalterably opposed to dependence on clinical methods for the diagnosis of syphilis. What does the detection of syphilis mean to the individual? First, it must mean that the attending physician is provoked into a type of examination of that individual which he does not, under any other ordinary circumstances, employ. I would not expect that in any routine preemployment or periodic physical examination the early signs of neurosyphilis would be detected unless that physician has been stimulated by the knowledge of positive serologic observations. One thing labor and the public should recognize is that, in the last analysis, this program for the prevention and cure of public health syphilis is for the benefit of the syphilitic. Whether or not there is any justification for not employing a syphilitic person will depend, I think, on the knowledge and the application of that knowledge by conscientious physicians and not on any other reasons. I think an important point for physicians in the handling of syphilis is thorough understanding of the mechanism by which syphilis impairs and interferes with healing, such as in fractures, wounds and so on. I don't believe there is any proof that syphilitic involvement locally, at the site of the injury, is of major importance; rather, we are dealing with an individual who has a constitutional defect, generally deep seated in his nervous system and sometimes in his vascular system.

DR. S. S. KETY, Picayune, Miss.: I have waited for some one to say something about syphilis in the South. I come from a small town, with small industries, but where syphilis has become a major problem, because of the lack of treatment and because of lack of education of the people. In the community from which I come the industrial physician is the family physician. He works closely with the board of health; he also runs the syphilis clinic. So there is no such thing as a patient not

being able to get treatment, if he will have it. The thing that has been left out of the Southern policy is forcing treatment. We offer treatment for 10 cents a week. We get patients to come for ten or twenty weeks and then they stop. We go out to see them ourselves and they say they have had enough. It is only recently that I have been able to get employers to listen to forced treatment, and they have consented to discuss that with me on my return from this congress. But the industrial worker can get treatment at a price comparable to his level of earning, whether it is in the North or in the South. But we must not talk only of industrial workers. There is his family. As a family physician I say Why stress the industrial worker when he has a wife and children? I went to the homes of women who were pregnant—this was before the government gave us our medicine—and offered to give them treatment for 25 cents, if they would just come and take the treatment. We got, on the average, one out of every ten cases. So the problem does not present itself of forcing treatment on the industrial worker but on an industrial worker's family.

DR. EARL D. OSBORNE, Buffalo: I rise to take exception strenuously to one or two remarks Mr. Zimmer made. I was stimulated by some of the things he said, and I am quite in agreement with some of them; in fact, with most of them. The benefit of a syphilis program to the employee was stressed repeatedly in the paper of myself and my co-workers, and in the other papers also. He is the man that is being benefited. Also the employer is being benefited, as is the public. It was with some reluctance that a plant owner, who employs some 1,200 workers, most of them in the age group from 20 to 35, put in a syphilis program. We found fifty-seven workers in his plant with syphilis, which was a percentage of a little less than 5. Those patients were carefully examined. And yet that isn't to the benefit of the employees! Whom is it benefiting? What would have happened to those individuals if their syphilis hadn't been found? Wouldn't the employees have gone on and developed late cardiovascular aneurysms and died a cardiovascular death? Many of them would have developed dementia paralytica and insanity. To whose benefit was it, but to theirs, to have a syphilis program? As to the cost, I am absolutely convinced that no one with syphilis need go without adequate treatment, and I don't believe 90 per cent of the individuals who come back and say they can't get treatment because they can't afford it. I know from personal experience that adequately trained individuals are willing to treat a patient for syphilis under one facility or another, whether in private practice, a semiprivate clinic or a free clinic, for whatever the patient can afford. I know it is generally the rule today, even among the most highly skilled syphilologists, that they will treat an individual with syphilis down to \$3 or even \$2 a week, provided he takes strenuous treatment and keeps at it.

DR. ALBERT E. RUSSELL, Chicago: I tried to stress in my paper the importance of routine blood testing. One of the big hospitals in this country reports that over 60 per cent of the patients who come there who have cardiovascular syphilis absolutely had no knowledge that they ever had syphilis. For that reason, and for many others, I believe that routine blood testing is important, no matter how good a diagnostician one might be. I should like to add a word about the cooperation I have had from labor groups. It is my particular duty and assignment to promote syphilis programs in industry. We sell the idea. We usually don't have to sell the plant physician, but we help him to sell the management in many places. Then we take the work into consideration. By approaching the heads of the unions or the leaders of their groups, we explain to them what it is about. We have had a most interesting and most happy result. In some instances the union has insisted that the management assure them they will carry out the program as recommended by the Surgeon General of the Public Health Service, and in so doing we have had nothing but amicable relations. In one of our programs the plant physician and even the personnel man said to us that they felt it brought the employer and the employee closer together, because the physician carried out his program in confidence between him and the worker. The management didn't know which were the positive cases. We have prepared articles for labor magazines, trade journals and plant papers and, even though we have started programs in plants where

there has been recent labor trouble, this syphilis program seems to be one that is going along nicely for the employee and the employer. We have not singled out the industrial worker alone to promote this syphilis program. Of the blood tests taken in Chicago last year, I believe 66,000 of them were listed as industrial workers. The industrial program is only a small part of the big syphilis program.

DR. HAROLD A. VONACHEN, Peoria, Ill.: I, like Dr. Osborne, was going to say nothing until Mr. Zimmer took the platform. The only difference between Dr. Osborne and myself is that he agrees with most of the things and I disagree with most of the things. What does industry gain by a syphilis program in comparison to what the human being gains? We have got to come in this country to the point at which we get away from class distinction both by the labor department and by everybody else connected with the government. I am speaking now as a private individual. If Mr. Zimmer would know his statistics, he would find that George Washington University, in his own city of Washington, D. C., took blood tests of its students long before there was any industrial program in the United States. He would find, by reading the women's journals, that many women's clubs had blood tests. Association of commerce members have their blood tested by their family physicians. I feel it is a grave injustice to industry for Mr. Zimmer to make the remarks he has made this afternoon.

DR. HARVEY BARTLE, Philadelphia: I am a little favorable to Mr. Zimmer's remarks. I think I have got in contact with labor pretty well in the last thirty-four years. I think the reaction expressed today should have some consideration. However, I should like to call attention to another group who have Wassermann reactions. They are the prospective bridegrooms. I am heartily in favor of routine Wassermann tests for every individual in the United States, irrespective of class. We shall get somewhere then. I don't know that we have a right to demand routine Wassermann tests among laborers any more than we have a right to demand an x-ray examination of the vertebral column or of the chest. We have just as many involvements in industry from those sources. The rehabilitation surgeon, of course, wouldn't want routine roentgenograms of the vertebral column taken because that would rob him of a lucrative practice. But there is an involving issue and, after all, there is a common sense approach to it. (To be continued)

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES

A two day session of the Board of Trustees was held at the headquarters of the Association on Thursday and Friday, February 15 and 16, preceded by a day and evening session of the Executive Committee on February 14, at which the business of the Association received careful consideration. Space permits only a brief abstract of these deliberations.

APPOINTMENTS

The following appointments were made to editorial boards of special journals and to councils and committees (unless otherwise stated the appointee succeeds himself):

Archives of Surgery, Dr. Evarts A. Graham. *Archives of Ophthalmology*, Dr. Francis Heed Adler. *American Journal of Diseases of Children*, Dr. A. Graeme Mitchell; Dr. Francis Scott Smyth, San Francisco, to succeed Dr. John C. Gittings, resigned. *Archives of Neurology and Psychiatry*, Dr. Stanley Cobb. *Archives of Otolaryngology*, Dr. John F. Barnhill. *Archives of Pathology*, Drs. S. B. Wolbach and Oscar T. Schultz; Dr. George H. Whipple, Rochester, N. Y., to succeed Dr. Alfred Stengel, deceased. *Archives of Dermatology and Syphilology*, Dr. Fred D. Weidman. *Archives of Internal Medicine*, Dr. John H. Musser. COUNCIL ON PHARMACY AND CHEMISTRY, Drs. Morris Fishbein, Perrin H. Long, G. W. McCoy and E. M. Nelson. COUNCIL ON PHYSICAL THERAPY, Drs. Frank R. Ober and Frank D. Dickson; Dr. Eben J. Carey, Milwaukee, to succeed Dr. Howard T. Karsner. COUNCIL ON FOODS, Drs. Morris Fishbein and Irvine McQuarrie. COMMITTEE ON SCIENTIFIC RESEARCH, Dr. Martin H.

Fischer; Dr. E. W. Goodpasture, Nashville, Tenn., to succeed Dr. C. C. Bass, resigned. COMMITTEE FOR THE PROTECTION OF MEDICAL RESEARCH, Dr. William J. Kerr and Rev. A. M. Schwitalla.

REPRESENTATIVE ON AMERICAN DOCUMENTATION INSTITUTE

Dr. Ludvig Hektoen was reappointed as representative of the American Medical Association on the American Documentation Institute.

REPRESENTATIVES TO MEETING OF CANADIAN MEDICAL ASSOCIATION

Delegates were selected to represent the American Medical Association at the meeting of the Canadian Medical Association, to be held in Toronto June 17 to 21.

COUNCIL ON INDUSTRIAL HEALTH

The terms of service of members of the Council on Industrial Health, suggested by the Council itself, received the approval of the board.

COMMITTEE ON AMERICAN HEALTH RESORTS

The Board authorized that arrangements be made to proceed with the work of the Committee on American Health Resorts.

APPROPRIATIONS

Appropriations were made for the conduct of the work of the various councils, bureaus and committees, as well as for scientific and therapeutic research.

REQUESTS FOR CUMULATED INDEXES OF SPECIAL JOURNALS

The Board decided not to authorize the publication at this time of cumulated indexes of any of the Association's special journals, since the response to notices published in four of those periodicals was too small to justify the undertaking.

TRANSFER OF INDUSTRIAL HYGIENE FROM UNITED STATES PUBLIC HEALTH SERVICE

The following preambles and resolution adopted by the Council on Industrial Health were approved by the Board:

WHEREAS, It has been brought to the attention of the Council on Industrial Health that certain proposed legislation contemplates the placing of responsibility for the development of industrial hygiene in an agency of the federal government other than that of the United States Public Health Service; and

WHEREAS, This Council believes that the interests of workers in industry will be best served by continuing this activity under the sponsorship of an agency which because of basic training in the broad aspects of industrial health assures attention to the varied interests involved; therefore be it

Resolved, That the Council on Industrial Health bring to the attention of the Board of Trustees matters regarding industrial hygiene incorporated in Senate bills 1620 and 2256, and that it is the sense of the Council that:

1. The interests of the industrial worker will best be served by continued concentration of industrial hygiene in the federal and state health departments, and that these bills as they affect industrial hygiene be opposed; but that

2. Due recognition be given to the desirability for cooperation with, as well as assistance from, other established agencies interested in this field having facilities for regulation and enforcement.

EXHIBITS AT NEW YORK SESSION

Arrangements were approved for the preparation of exhibits of the Council on Medical Education and Hospitals, Council on Pharmacy and Chemistry, Council on Physical Therapy and Council on Industrial Health and of the special journals at the New York session of the Association.

A. M. A. DAY AT NEW YORK WORLD'S FAIR

Arrangements for A. M. A. Day at the New York World's Fair during the New York session received the approval of the Board.

SPECIAL ISSUE OF ARCHIVES OF OPHTHALMOLOGY IN HONOR OF DR. F. H. VERHOEFF

The Board approved the publication of a special issue of the *Archives of Ophthalmology* in honor of Dr. F. H. Verhoeff, Boston, who for a number of years was professor of ophthalmic research at Harvard Medical School, and who recently retired.

INVESTMENTS

Considerable time was devoted by both the Finance Committee and the Board of Trustees to the matter of investing the funds of the Association.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Tuberculosis Institute.—An Indian Service Tuberculosis Institute was held at the Navajo Medical Center, Fort Defiance, February 12-14, attended by 121 federal, state and county health organization employees. Those conducting the program included Dr. Esmond R. Long and Miss Margaret Smith, of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia; Miss Rosalie Peterson, R.N., of the Office of Indian Affairs, Washington, D. C.; Drs. Ralph B. Snavely, San Francisco; Estella Ford Warner, Albuquerque, N. M., and William W. Peter, Window Rock. Physicians and nurses from eleven Indian agencies in the Southwest also participated in the program. There are three tuberculosis sanatoriums with a bed capacity of 200 for a population of 50,000 Indians on the Navajo reservation of 25,000 square miles; there are also nine general hospitals occasionally admitting tuberculosis patients. Supplementing the work of these twelve institutions, field work, primarily to discover early cases of tuberculosis, is conducted by Dr. Horace P. Mahan, Winslow; Miss Esther Sandstrom, R.N., and Miss Violet Sobers, R.N.

ARKANSAS

Postgraduate Course.—The eighth two day course of postgraduate instruction, sponsored by the state medical society and the University of Arkansas School of Medicine, Little Rock, was held at the medical school, January 24-25. The guest speakers included: Drs. Henry H. Turner, Oklahoma City, on "Hypothyroidism"; Ferdinand C. Helwig, Kansas City, Mo., "Relationship of Trauma to Tumors," and Charles F. Geschickter, Baltimore, "Tumors of Bones." Other speakers, all of Little Rock, were:

Dr. Harvey Shipp, Operative Treatment in Pulmonary Tuberculosis.
Dr. Hoyt R. Allen, Diagnosis and Treatment of Common Ailments of the Rectum and Anal Canal.

Dr. Merlin J. Kilbury, Interpretations of Laboratory Findings.

Dr. Raymond L. Gregory, Frequent Mistakes in the Diagnosis of

Dr. " " of the Stomach: Its Incidence in

Dr. " " and Findings in the X-Ray Examination of the Lower Part of the Back.

Dr. Joseph Franklin Shuffield, Low Back Pain from the Standpoint of the Orthopedic Surgeon.

Dr. Herbert Fay H. Jones, Low Back Pain from the Standpoint of the Urologist.

Dr. Joseph H. Sanderlin, Low Back Pain from the Standpoint of the Gynecologist.

Dr. Helwig addressed the dinner meeting on "Medicolegal Aspects of Alcoholic Intoxication."

DISTRICT OF COLUMBIA

Postgraduate Course in Ophthalmology.—The fourth annual postgraduate course in ophthalmology of the George Washington University School of " " will be held March 25-30. A practical course limited to twenty-five participants in surgery, pathology and orthoptics will be held March 19-23. Additional information may be obtained from the school, 1335 H Street Northwest, Washington.

Health Instruction for Employees.—The District Works Projects Administration opened a six weeks' health institute, January 15, to provide instruction in the essential facts of everyday health problems for 3,700 employees of its professional and service divisions, according to *Medical Annals*. Cooperating with the WPA are the district health department, the speakers' bureau of the Medical Society of the District of Columbia and the Medico-Chirurgical Society.

Postgraduate Courses.—The committee on postgraduate education of the Medical Society of the District of Columbia is conducting a series of postgraduate courses. The first group of lectures constituted a course on syphilology with the following speakers: Dr. John A. Kolmer, Philadelphia, January 15, on "Principles in Diagnosis and Treatment of Syphilis" and Reuben L. Kahn, Sc.D., Ann Arbor, Mich., January 22, "Interpreting Serologic Reactions in Syphilis." Other subjects to be covered in subsequent courses, provided the interest is sufficient, include psychoneuroses in general practice, office surgical procedures, cutaneous diseases in general practice, obscure fevers and preventive pediatrics.

Society News.—Dr. Raymond L. Pfeiffer, New York, discussed "Lesions of Chiasm" before the Washington Ophthalmological Society, February 12.—At a meeting of the George Washington University Medical Society, January 20, Dr. William Wayne Babcock, Philadelphia, discussed abdominal surgery.—Lyman J. Briggs, Ph.D., director of the bureau of standards, discussed "Developments in Modern Physics and Their Relation to Medicine" before the Academy of Medicine of Washington, February 29.—Dr. Hugo Roesler, Philadelphia, will discuss "Roentgenological Aspects of Cardiovascular Disease" before the Washington Heart Association, April 10.—At a meeting of the Washington Society of Pathologists, January 6, the speakers included Drs. Harold E. Ragle on "Tumor of the Sacrococcygeal Region" and Janvier W. Lindsay, "Carcinoma of the Esophagus; Early Carcinoma of the Larynx."

ILLINOIS

Personal.—Dr. Edward F. Dombrowski, managing officer of the Chicago State Hospital, was recently made president of the Conference of Managing Officers of the state department of public welfare.—Dr. Eugene J. Chesrow, Chicago, has been appointed superintendent of the Oak Forest Infirmary, newspapers reported.—The McDonough County Medical Society recently presented to Dr. Elizabeth R. Miner, Macomb, a check as a token of its appreciation of her work as secretary of the society for the last fifteen years. Dr. Miner was elected for life to this office but has resigned. She and her husband will spend their winters in Florida. She has been delegate to the state medical society for twenty years and has held every office in the county society as well as the office of second vice president of the state society.

Chicago

Midwinter Clinical Meeting.—The South Side Medical Assembly, the annual midwinter clinical meeting of the Calumet, South Chicago, South Side, Southern Cook County and Stock Yards branches of the Chicago Medical Society, was held, February 14. Sessions were devoted to discussions of pneumonia, modern treatment of urologic diseases, sulfanilamide and its compounds, obstetrics, cancer, hormones, fractures and cardiac diseases.

Dr. Bacon Honored.—A testimonial dinner was held in honor of Dr. Charles Sumner Bacon, February 6, in recognition of his sixteen years' service as chief of staff at the Booth Memorial Hospital, which is under the auspices of the Salvation Army. He is 83 years of age. The hospital cares for unwed mothers and their babies. Services of the staff are volunteered. Dr. Bacon, who graduated at Northwestern University Medical School in 1884, served as professor and head of the department of gynecology and obstetrics at the University of Illinois College of Medicine for many years and has been emeritus professor since 1926. He was president of the Illinois State Medical Society, 1905-1906, and of the Chicago Gynecological Society, 1902-1903 and 1923-1924. The Bacon lectures at the University of Illinois are named in his honor.

Society News.—The Chicago Society of Internal Medicine was addressed, January 22, by Drs. Robert G. Bloch and Abraham J. Kauvar on "Schaumann's Disease (Boeck's Sarcoid)"; Henry T. Ricketts, "The Constancy of Action of Protamine Zinc Insulin," and James G. Carr, Alexander Saunders and Gilbert H. Marquardt, "Studies of Angina Pectoris."—A symposium on syphilis constituted the program of the Chicago Laryngological and Otolological Society, February 5; the speakers were Drs. Lawrence J. Lawson, Evanston; John F. Delph, Francis E. Seneat, James H. Mitchell, Samuel J. Pearlman and Joseph Welfeld.—Among others, Drs. Roland S. Cron, Harold W. Shutter and Albert H. Lahmann, Milwaukee, discussed "Epidemic Infectious Diarrhea of the Newborn" before the Chicago Gynecological Society, February 16.—Among others, Dr. Walter P. Blount, Milwaukee, addressed the Chicago Orthopaedic Society, February 9, on "Osteotomy of the Humerus in the Treatment of Obstetrical Shoulder Lesions."

KANSAS

New Director of Tuberculosis Control.—Dr. Floyd C. Beelman, Wichita, for three years health officer of Sedgwick County, has accepted the position of director of the division of tuberculosis control of the Kansas State Board of Health. Dr. Henry H. Asher has succeeded Dr. Beelman in Sedgwick County.

University News.—Dr. John F. Fulton, New Haven, Conn., lectured at the Museum of Medical History, University of Kansas Hospitals, Kansas City, February 5, on "The History

of Physiology." Dr. Franklin G. Ebaugh, Denver, delivered the William W. Root Lecture, February 9, on "The Psychoneuroses in the General Practice of Medicine."

Annual Postgraduate Clinics.—The University of Kansas School of Medicine will hold its annual postgraduate clinics March 18-21. Presentation of clinical cases with emphasis on therapy will be a feature of the courses. An effort will be made to demonstrate therapeutic procedures that the general practitioner can apply to his office practice. Additional information may be obtained from Dr. Hugh L. Dwyer, chairman, committee on postgraduate clinics, University of Kansas School of Medicine, Kansas City.

MARYLAND

Dr. Lomas Resigns from University Hospital.—Dr. Arthur J. Lomas has resigned as head of the University Hospital, Baltimore, after holding the position for sixteen years, according to *Modern Hospital*. He plans to serve as administrative consultant to five Catholic hospitals in Maryland: Mercy, St. Joseph's, Bon Secours and St. Agnes hospitals, all of Baltimore, and the Allegany Hospital, Cumberland. Dr. John E. Savage is acting medical superintendent of the University Hospital.

Society News.—A joint meeting of the Baltimore City Medical Society and its radiologic section was addressed, March 1, by Dr. William P. Healy, New York, on "Radiation and Surgery in the Treatment of Carcinoma of the Uterine Cervix and of the Corpus." The society will be addressed, March 15, by Drs. Tibor de Cholnoky, New York, on "Rehabilitation in Advanced Cancer," and Alston E. Morrison, "Diagnosis of Nonopaque Foreign Bodies in the Lower Respiratory Tract."—The Osler Historical Club was addressed in Baltimore, March 12, by Dr. Frederik B. Bang, Baltimore, on "Influence of Bacteriologic Discoveries on the Epidemiologic Theories of the Nineteenth Century," and Dr. John McW. McDonald, "Life and Works of Ramazzini."—Dr. Arthur M. Shipley discussed "Treatment of Gunshot and Stab Wounds of Chest and Abdomen" in a clinic before the Howard County Medical Society in Baltimore, January 23.

MINNESOTA

Personal.—Dr. Harold S. Diehl, dean of medical sciences, University of Minnesota Medical School, Minneapolis, has been appointed a member of the National Advisory Health Council of the U. S. Public Health Service.

Society News.—A symposium on painful conditions about the head and face was presented before the Ramsey County Medical Society, February 26, in St. Paul, by Drs. Gordon R. Kamman, Gordon E. Strate and Wallace P. Ritchie, St. Paul.—The Minnesota Pathological Society was addressed in Minneapolis, February 20, by Drs. James S. McCartney on "Dissecting Aneurysm of the Aorta" and Lawrence Berman, "Cancer as a Cause of Death in Minnesota."

MISSOURI

Society News.—Dr. Allen O. Whipple, New York, will discuss application of chemistry to the preoperative and postoperative care of surgical patients before the Kansas City Academy of Medicine, March 15.—Dr. Irwin I. Rosenthal, St. Joseph, addressed the Buchanan County Medical Society in St. Joseph, February 7, on "Recent Advances in Anesthesia."—The Kansas City Society of Ophthalmology, Otolaryngology, Rhinology and Laryngology was addressed, January 18, by Drs. Harry S. Gradle, Chicago; Norton Canfield, New Haven, Conn.; Andrew A. Eggston, New York, and Walter Hughson, Abington, Pa. Drs. Gradle and Eggston addressed the dinner meeting on "Glaucoma Capsulare" and "Pathology of Mastoiditis, Petrositis and Meningitis" respectively.—At a meeting of the Kansas City Obstetrical and Gynecological Society, January 11, the speakers were Drs. Richard G. Helman on "The Undilated Cervix"; Herbert F. Vanorden, "Term Delivery in a Patient with Deformed Pelvis Caused by Multiple Fractures," and Joseph G. Webster, "Case of Toxemia of Pregnancy."

Pneumonia Control Program.—The state department of health recently has begun a program to control pneumonia. At present the program will be limited to the eight counties maintaining full time public health units but will be extended into other parts of the state as soon as facilities permit. In January, the department furnished the local units with materials for typing and sulfapyridine and antipneumococcic serums for treatment. Physicians may receive the drugs for use in indi-

gent cases. This year Missouri received government funds for pneumonia control work. Regional conferences of public health personnel were held in December to explain the new program with Dr. Henry A. Holle, regional consultant in pneumonia, U. S. Public Health Service, showing films on diagnosis and therapy.

Medicomilitary Symposium.—The annual spring medicomilitary symposium will be in the Jackson County Medical Society's Auditorium in the Municipal General Hospital, Kansas City, March 14-15. The program lists the following guest speakers:

Dr. Ralph A. Kinsella, St. Louis, Physical Diagnosis in Acute Diseases of the Chest.

Dr. Hiram Winnett Orr, Lincoln, Neb., Relationship of Wound Treatment to the Care of Compound Fractures.

Dr. Alfred I. Folsom, Dallas, Texas, Some Overlooked Facts in the Treatment of Chronic Gonorrhea.

Dr. Arthur A. Zierold, Minneapolis, Head Injuries.

Dr. Walter A. Carlson, Randolph Field, Texas, Aviation and Its Medical Problems.

Dr. Frederick A. Jostes, St. Louis, Conservative Treatment of Low Back Disability.

A joint meeting with the Jackson and Wyandotte county medical societies will be held March 14.

MONTANA

Tularemia Infection in Streams.—The staff of the Rocky Mountain Laboratory of the U. S. Public Health Service recently reported that three Montana streams have been found to be contaminated with *Bacterium tularensis*. The discovery was made in the course of studies of epizootic tularemia in beaver. Two of the streams are flowing creeks and the other at certain times of the year consists of a succession of pools. Three samples taken over a period of twenty-eight days showed contamination and guinea-pigs that received the water became infected.

NEW JERSEY

Society News.—Dr. Arthur M. Fishberg, New York, addressed the Hudson County Medical Society, Jersey City, February 6, on "Recent Advances in Cardiovascular-Renal Diseases."—Dr. Edward W. Sprague, Newark, was elected president of the Society of Surgeons of New Jersey at the annual meeting in Camden, January 31.—Dr. Priscilla White, Boston, addressed the Atlantic County Medical Society, Atlantic City, February 9, on recent advances in diabetes.—Dr. E. Arthur Whitney, Elwyn, Pa., addressed the Cumberland County Medical Society, Vineland, February 13, on "Medical Aspects of the Care of the Feeble-minded."—Dr. Paul Geary, Plainfield, addressed the Morris County Medical Society, Morris Plains, February 15, on "Nontuberculous Pulmonary Abscesses."

NEW YORK

Personal.—Dr. Harvey S. Kinne, Albany, recently an assistant district health officer on the staff of the state health department, has been appointed health commissioner of Cortland County.

Society News.—Dr. Burrill B. Crohn, New York, addressed the Medical Society of the County of Albany in Albany, February 28, on peptic ulcer.—Dr. Lewis M. Hurxthal, Boston, addressed the Dutchess County Medical Society, Poughkeepsie, February 14, on endocrinology.—Dr. Edward G. Waters, Jersey City, N. J., addressed the Onondaga County Medical Society, Syracuse, March 5, on "Injuries to the Birth Canal During Parturition."

New York City

Dr. Barringer Honored.—Dr. Emily Dunning Barringer was honored with a dinner, March 2, by the staff of the Kingston Avenue Hospital on the occasion of her retirement as director of gynecology after twenty-one years of service. Speakers were to include: Drs. Terry M. Townsend, president of the Medical Society of the State of New York; Nathan B. Van Etten, President-Elect of the American Medical Association; Sigismund S. Goldwater, commissioner of hospitals; Elise D. S. L'Esperance, of the New York Infirmary for Women and Children; Thurman B. Givan, visiting physician, and Hyman Strauss, visiting gynecologist, Kingston Avenue Hospital; Anna W. Williams, former assistant director of laboratories, New York City Health Department; Robert M. Lewis, associate clinical professor of obstetrics and gynecology, Yale University School of Medicine, New Haven, Conn.; Miss Julia K. Jaffray, secretary of the National Committee on Prisons and Prison Labor; Hon. Anna M. Krosc, city magistrate, and Dr. Barringer.

MEDICAL NEWS

901

Society News.—Drs. Josephine B. Neal and Joseph J. Bunim addressed the Medical Society of the County of New York, February 26, on "Chemotherapy in Meningitis" and "Use of Sulfapyridine in Treatment of Pneumococcus Pneumonia" respectively.—At a meeting of the New York chapter of the National Gastroenterological Association, February 19, the staff of Memorial Hospital for the Treatment of Cancer and Allied Diseases presented a symposium on gastric cancer. The speakers were Drs. James Ewing, Cornelius P. Rhoads, Gordon P. McNeer, Juan M. Jimenez, George T. Pack and Edward M. Livingston.—Drs. Dana W. Atchley, New York, and Frederick A. Collier, Ann Arbor, Mich., addressed the New York Academy of Medicine, March 7, on medical and surgical considerations, respectively, of "Clinical Manifestations and Management of Disturbances in Water Metabolism." Dr. John P. Peters, New Haven, Conn., was a discussant.—At a combined meeting of the section of neurology and psychiatry of the New York Academy of Medicine and the New York Neurological Society, March 12, Dr. Eli Jefferson Browder will speak on "Spinal Epidural Infections: Surgical and Pathological Consideration" and Dr. Francis A. Echlin, Montreal, Que., "Focal Cerebral Ischemia and Reactive Gliosis Following Experimental Vascular Spasm."

rence Selling, Portland, addressed the Polk-Yanhill-Marion Counties Medical Society in Salem, February 13, on "Herniation of the Intervertebral Disk" and "Hypertrophy of the Ligamentum Flavum."

PENNSYLVANIA

Advisory Health Board Appointed.—Gov. Arthur H. James recently appointed new members of the advisory board to the state department of health. The appointees were Drs. George Morris Piersol, professor of medicine, University of Pennsylvania Graduate School of Medicine, Philadelphia; David W. Thomas, Lock Haven, president of the Medical Society of the State of Pennsylvania; William Gray Turnbull, superintendent of the Philadelphia General Hospital; Donald Guthrie, chief surgeon of the Packer Hospital, Sayre; Ivor Griffith, Pharm.D., dean of the Philadelphia College of Pharmacy and Science, and Archibald Nance, Pittsburgh, a civil engineer.

Philadelphia

Personal.—Dr. Basil R. Beltran has resigned as medical director and chief surgeon of the Eastern State Penitentiary Hospital, which was to be opened for patients on March 7. He will devote his time to his work as surgeon in chief at Nazareth Hospital, which was to be opened for patients on March 7.

Hospital News.—Temple University Hospital dedicated a new floor and other improvements in the building, February 14. The new fifth floor has thirty-three rooms, principally for maternity patients. Operating rooms have been air conditioned, and soundproofing was placed in private and semiprivate rooms.

More Gifts to the University.—The University of Pennsylvania recently announced additional gifts to its bicentennial fund. Among those for medical purposes are the following:

- Eldridge R. Johnson, \$10,000 for the Johnson Foundation for Research in Medical Physics, which he established.
- Mrs. Arthur W. Thompson, \$6,000 to the Thompson Vitamin Research Fund.
- National Committee on Maternal Health, \$3,000.
- National Tuberculosis Association, \$2,287.
- Rockefeller Foundation, \$2,650.
- Josiah Macy Jr., Foundation, \$1,500.
- Mead Johnson & Co., \$1,500.
- International Cancer Research Foundation, \$1,334.
- John Frederick Lewis Jr., Philadelphia attorney, \$25,000 added to a previous gift of \$25,000 by Mr. Lewis and his brother to provide a floor for ophthalmology in the new hospital unit now under construction.
- Mrs. Lewis H. Adler, \$1,000, and Miss Julia Lewis, \$600 for the department of ophthalmology.

OHIO

Inter-County Meetings.—The Erie County Medical Society is presenting its second series of clinical lectures in Sandusky, with members of adjacent county societies as guests. Following is the series:

January 17, Dr. Henry J. John, Cleveland, Principles of Treatment of Diabetes.
February 14, Dr. Clarence W. Engler, Cleveland, Sinusitis.
March 13, Dr. James L. Reyer, Cleveland, Operative Treatment of Uterine Prolapse, Cystocele and Rectocele.
April 17, (1) Dr. Walter G. Stern, Cleveland, Is Prepaid Medical Insurance Necessary Today? If So, A Practical Plan for Same; (2) The Estimation of Disability Following Injury, and (3) Milton Landy, referee of the State Industrial Commission, The Legal Phase of Statewide Prepaid Medical Insurance.

Society News.—Dr. James L. Wade, Parkersburg, W. Va., addressed the Washington County Medical Society, Marietta, January 10, on myasthenia gravis.—Drs. Carl E. Evans and John E. Hendricks, Newark, addressed the Tuscarawas County Medical Society, Newark, January 11, on "Surgical Considerations of the Abdominal Cavity" and "Removing Foreign Bodies from the Lungs" respectively.—Dr. Charles R. Austrian, Baltimore, addressed the Academy of Medicine of Cleveland, February 16, on "Chronic Nontuberculous Infections of the Lungs."—Dr. Leroy U. Gardner, Saranac Lake, N. Y., addressed the Academy of Medicine of Cincinnati, February 20, on "Pneumoconiosis."—Dr. Robert L. Schaefer, Detroit, addressed the Summit County Medical Society, Akron, February 6, on "Diagnostic and Therapeutic Endocrine Facts of Value to Patient and Physician."

OREGON

Dr. Kinney's Ninetieth Birthday.—Dr. Alfred C. Kinney, Seaview, Wash., first and fiftieth president of the Oregon State Medical Society, was entertained at a luncheon in Portland, January 30, planned and attended by the four other surviving members of the first state board of health, celebrating his ninetytieth birthday. Dr. Kinney related that the bill creating the board of health was written by Dr. Oliver Wendell Holmes. While studying in Massachusetts, Dr. Kinney met Dr. Holmes, brought the bill, modeled on the Massachusetts statute, home in his pocket and gave it to a legislator for introduction in 1872. It was not enacted, however, until 1903. The other original members who attended the luncheon were Drs. Andrew C. Smith, Charles J. Smith, Edward Allen Pierce, Portland, and Willis B. Morse, Salem.

Society News.—A symposium on "Fluid Administration by Parenteral Methods" was presented before the Multnomah County Medical Society, Portland, February 21, by Drs. Albert W. Holman, Louis P. Gambec, Homer P. Rush and Thomas D. Robertson.—Dr. Simeon T. Cantril, Seattle, addressed the Lane County Medical Society, Eugene, February 16, on radiation therapy.—Dr. Chester A. Bump, Newberg, discussed treatment of burns at a meeting of the Yamhill County Medical Society, McMinnville, February 6.—The Umatilla County Medical Society was recently reorganized with Dr. Joseph P. Brennan, Pendleton, as president and Dr. Theodore M. Barber, Pendleton, secretary. At a meeting, February 13, Dr. Richard H. Wilcox, Pendleton, county health officer, spoke on "Regulations Pertaining to Communicable Diseases" and W. C. Perry, attorney, on "The Doctor on the Witness Stand."—Dr. Lau-

SOUTH CAROLINA

Society News.—Dr. Joseph M. Feder addressed the Anderson County Medical Society, Anderson, January 10, on "Investigation of Hepatic Function and the Evaluation of Vitamin K Therapy."—Dr. De Forest C. Jarvis, Barre, Vt., addressed the Greenville County Medical Society, Greenville, January 10, on "Biochemistry in Everyday Medicine from a Research Group Study."—Drs. Richard W. TeLinde, Baltimore, and George R. Wilkinson, Greenville, addressed the society, February 5, on "Organic Causes of Uterine Bleeding."—Dr. Wells P. Eagleton, Newark, N. J., addressed the Columbia Medical Society, January 8, on "A Philosophical Review of the Advances in the Treatment of Meningitis."—Dr. Frank P. Coleman, Columbia, addressed the Edisto Medical Society, Orangeburg, January 24, on "Water Balance in the Medically and Surgically Sick."—Dr. Julian M. Ruffin, Durham, N. C., addressed the Medical Society of South Carolina, Charleston, January 9, on "Gastroscopy."—At a meeting of the Oconee County Medical Society in Seneca, January 4, Dr. Wofford E. Baldwin, Wallhalla, county health officer, discussed a plan to establish contraceptive clinics and the syphilis control campaign, and Dr. Rowland F. Zeigler Jr., Seneca, led a round table discussion on sulfapyridine treatment of pneumonia.

TEXAS

Hospital News.—Colonel and Mrs. J. W. Neal, Houston, recently established a trust fund of \$100,000 for Memorial Hospital, Houston, as a memorial to their son who died recently. The interest is to be used to provide x-ray treatment for those unable to pay for it.

New Health Officers.—Dr. Clark E. Phillips, Orange, has been appointed health officer of Orange County to succeed the late Dr. Jefferson D. Yates.—Dr. Cecil G. Yarbrough Jr., Midland, has been appointed health officer of a new Midland city and county health unit.

Personal.—Dr. and Mrs. Robert W. Noble, Temple, recently celebrated their golden wedding anniversary. Dr. Noble was formerly a member of the state board of health and has been health officer of Temple for many years, according to the *Texas State Journal of Medicine*.—Dr. Green L. Davidson, Wharton, was recently elected president for life of the Wharton-Jackson Counties Medical Society.

Special Society Meeting.—Dr. James W. Ward, Greenville, was elected president of the Texas Ophthalmological and Otolaryngological Society at its annual meeting in Houston recently. The guest speakers were Drs. Dean M. Lierle, Iowa City, who discussed "Surgical Sinusitis" and "Vertigo," and Daniel B. Kirby, New York, "Difficulties During Cataract Extractions" and "Difficulties After Cataract Extractions."

UTAH

A Case of Plague.—The U. S. Public Health Service was informed, February 6, of a case of bubonic plague in Utah. The disease was in a man aged 29 who was thought to have been infected when skinning a coyote.

GENERAL

New Officers of National Health Council.—Dr. Kendall Emerson, managing director of the National Tuberculosis Association, New York, has been elected president of the National Health Council, it was announced, February 21. Dr. Reginald M. Atwater, executive secretary of the American Public Health Association, is the new vice president and Miss Dorothy Deming, general director of the National Organization for Public Health Nursing, secretary.

Film on Hearing Aids.—"Life Begins Again" is the title of a motion picture prepared by the Western Electric Company to demonstrate the possibilities of aid to persons with hearing defects. The picture dwells particularly on problems in school children and shows the correct procedure for discovering deficiencies in hearing by means of the audiometer. Included in the film is an animated sequence which demonstrates how the human auditory system works. Theaters may obtain the film without charge.

General Pershing Receives Snow Medal.—General John J. Pershing was awarded the William Freeman Snow Medal for distinguished service to mankind at the annual meeting of the American Social Hygiene Association in Chicago, February 1. Major Gen. Merritte W. Ireland, former surgeon general, U. S. Army, made the presentation and General Pershing accepted by telephone from Tucson, Ariz. General Pershing was the first chairman and one of the founders of the national antisiphilis committee sponsored by the social hygiene association in 1937. This is the third presentation of the medal, which honors Dr. Snow for his long service as general director of the association.

Pacific Coast Surgical Meeting.—The annual meeting of the Pacific Coast Surgical Association will be held in Portland, Ore., April 3-6, under the presidency of Dr. Richard B. Dillehunt, Portland. The guest speakers will be:

- Dr. Andrew A. Matthews, Spokane, Wash., Cancer of the Breast.
- Dr. Albert J. Scholl, Los Angeles, Utereral Stones, A Nonsurgical Method of Treatment.
- Dr. Herbert S. Chapman, Stockton, Calif., Unusual Tumors of the Endocrine System.
- Dr. Robertson Ward, San Francisco, Appendicitis with Complications; Reduction of Mortality by Continuous Gastric Lavage.
- Dr. Charles T. Sturgeon, Los Angeles, Pulsion Diverticula of the Hypopharynx.

Courses Sponsored by College of Physicians.—The American College of Physicians announces its third annual series of courses for its fellows and associates, arranged through the cooperation of the directors and the institutions at which the courses are given. The courses are as follows:

- General medicine, University of Michigan Medical School and Hospital, Ann Arbor, Dr. Cyrus C. Sturgis, director, March 18-30.
- Medicine in industry, Henry Ford Hospital, Detroit, Dr. Frank J. Sladen, director, March 25-30.
- Allergy, Roosevelt Hospital, New York, Dr. Robert A. Cooke, director, March 19-30.
- The blood and the blood cell forming organs in disease, Ohio State University College of Medicine, Columbus, Dr. Charles A. Doan, director, March 25-29.
- Cardiovascular disease, State University of Iowa College of Medicine, Iowa City, Dr. Fred M. Smith, director, March 25-30.

League Against Rheumatism Not Dissolved.—Although the bureau of the Ligue internationale contre le rhumatisme in Amsterdam has been closed, as previously announced in *THE JOURNAL* (Nov. 11, 1939, page 1821), it is announced by the president, Dr. Ralph Pemberton, Philadelphia, that the league is not dissolved and that the present structure and personnel of the league should be maintained for the duration of

the war, ready to resume activities as soon as circumstances permit. Formal dissolution of such a body as the league must depend on formal action by its constituent members or a body acting for them, and this step has not been taken.

Societies for Experimental Biology.—The Federation of American Societies for Experimental Biology will hold its annual meeting at the Roosevelt Hotel, New Orleans, March 13-16. The federation is composed of the American Physiological Society, the American Society of Biological Chemists, Inc., the American Society for Pharmacology and Experimental Therapeutics, Inc., and the American Society for Experimental Pathology. The scientific session will open with a joint meeting. Symposia held in the various sections will include the following subjects: blood coagulation, muscle, biochemistry of the lipids; hormones; tissue respiration; stable and radioactive isotopes as tracers in biologic research; recent advances in therapeutics. The annual dinner will be Friday evening and business meetings of all societies will be held Thursday and Friday.

Government Services

General Marietta Appointed Assistant Surgeon General

Brig. Gen. Shelley U. Marietta, Medical Corps, U. S. Army, has been appointed assistant to the Surgeon General of the Army. General Marietta was graduated from the University of Illinois School of Medicine, Chicago, in 1909 and from the Army Medical School in 1912. He has served at various stations in the United States, in the Philippine Islands, in France and in Hawaii.

New Members of Veterans' Medical Council

At a recent conference of the Medical Council, Veterans' Administration, the following were elected new members: Drs. Alfred W. Adson, Rochester, Minn.; John Alexander, Ann Arbor, Mich.; John S. Coulter, Chicago; Kendall Emerson and Frederick W. Parsons, New York; Elliott P. Joslin and Harry C. Solomon, Boston; David R. Lyman, New Haven, Conn.; James A. Lyon, Edwin A. Merritt and Winfred Overholser, Washington, D. C., and Lowell J. Reed, Ph.D., Baltimore. A new group, counselors emeritus, was created, composed of Drs. Edward R. Baldwin, Saranac Lake, N. Y.; Sigismund S. Goldwater, New York; Allen K. Krause, Dean Lewis and Winford H. Smith, Baltimore; Joseph W. Schereschewsky, Atlanta, Ga., and Ray Lyman Wilbur, Stanford University, Calif.

Medical Division Established in Federal Trade Commission

Announcement was made, February 8, of the establishment of a medical advisory division in the Federal Trade Commission in Washington to have the same status as other divisions. The director of the new unit will be Dr. Knox E. Miller, senior surgeon, U. S. Public Health Service, who has been on duty with the commission since 1938 as technical consultant to advise on medical and other claims made in advertising of foods, drugs and cosmetics. The medical advisory division will take the place of the medical advisory section and the following personnel in the advisory section has been transferred to the division: Drs. Miller, Charles F. Church and Frederick C. Warnshuis, Miss Beatrice Ruffin and Mrs. Frances Tatum. The change was effective immediately.

Military Medicodental Training Course

The third annual military medicodental training course at Chicago for medical department reserve officers will be held by the sixth corps area March 31-April 13. The course will be conducted under the direction of the corps area surgeon, Col. Paul W. Gibson, with the cooperation of the medical and dental schools of Illinois, Chicago, Loyola and Northwestern universities. It is designed to increase the military and professional proficiency of reserve officers of the medical, dental, veterinary and medical administrative corps. The morning hours will be devoted to professional work in the schools, hospitals and clinics connected with the participating universities. The afternoon and special evening sessions will be devoted to problems connected with the operation and functioning of the medical service in war. The military courses for the current year will be especially concerned with problems of mobilization as they affect the medical department of the army.

Foreign Letters

LONDON

A Medical Library for the Army in France

The blood transfusion service and surgical research service of the army were initiated by the Royal College of Surgeons through the conservator, Col. John Beattie, and are under his direction. There is a unit in France with its research laboratory, which is under the control of the pathologic curator of the college, and twelve of the college staff work in the laboratory. Colonel Beattie has reported that the unit in France is handicapped by lack of current medical and scientific periodicals. In view of the relations of the college to the army blood transfusion service it has been suggested that the council might establish a library of current periodicals for the use of the unit in France. The *British Medical Journal* has gone further and pointed out that the suggestion of a library for research workers leads directly to the wider possibility—a reference library, which should be available to all officers of the medical service in France.

Tuberculous Patients in Wartime

A previous letter noted the trouble which has arisen from the discharge of tuberculous patients from sanatoriums to make room for the large number of casualties expected from air raids. Mr. Walter Elliot, minister of health, has received a deputation on the subject from the Socialist Medical Association. Referring to the complaint that on the outbreak of war patients had been sent home from sanatoriums when not in a fit state for discharge, he said that this could have arisen only from a misunderstanding of the instructions issued by the ministry. The desire was that every tuberculous patient in need of inpatient treatment should receive it, and instructions had been given to that effect. Since November 1, 125 tuberculous institutions had been released from their obligations to the Emergency Medical Service so that they might devote all their accommodation to their normal functions. More than two thirds of the 28,000 beds provided for the treatment of tuberculosis in England and Wales were still available for that purpose. Since about 3,000 were vacant, the admission of new cases should not present any difficulty.

American Offers of Help for the Wounded

Since the outbreak of war the British medical authorities have received generous offers of help from the United States. Some came from official organizations like the American Red Cross, others from groups of sympathizers with the allied cause and others from individuals. They included offers to establish hospitals in France or England and to provide surgical teams or ambulances and medical equipment. The medical service of the British army has had constantly in mind the experience of the last war and has made plans to deal with the maximum number of casualties calculated by the general staff on the basis of the extent and nature of the military operations to be undertaken, with an ample margin of reserve. Accordingly, every contingent of troops leaving our shores is accompanied by its allotted quota of military hospitals, on the scale laid down, while medical reserves of every description are held in both France and England to meet eventualities.

For the present, therefore, the proffered American help would be most useful not in the form of organized hospitals or of personnel but in the provision of extra medical equipment and stores, including motor ambulance transport, or of funds for the purchase of such supplies and materials. There is an ample supply of British physicians and surgeons of the highest attainments in every specialized branch; indeed, only a proportion of

those who have offered their services could be accepted. Later in the war, when the reserves of hospital accommodation and of medical personnel may be fully drawn on, reinforcements from America would be gratefully received, without overlapping of effort.

The Radiation Treatment of Metastases

At the Section of Radiology of the Royal Society of Medicine, Dr. F. M. Allchin opened a discussion on the treatment of metastases. He said that the attack on them was the crucial point in the treatment of cancer. It was generally acknowledged that in its early stages cancer was a localized disease and could be combated by accepted methods, among which radiotherapy was of increasing importance. To obtain the best results in the treatment of metastases, all forms of treatment should be considered and sometimes two or three forms of radium treatment should be combined. Investigation of the state of the blood before treatment was begun and at regular intervals was important. Sterilization of women under the age of the menopause was of the utmost importance in cases of cancer of the breast. Metastases from breast cancer were always sensitive to radiation, while those from the prostate or the kidney varied in their response. In breast deposits a satisfactory result could often be obtained from small doses, and in his experience large doses were not called for. The scanty literature on the subject suggested that metastases were less responsive to full radiation doses than the primary growth. The response depended, among other factors, on the histologic structure, but in many cases no prediction as to response could be made. Treatment should aim at full doses consistent with the general condition of the patient.

Dr. M. C. Tod said that the methods which might be considered curative were regional therapy for tumors of high sensitivity and localized therapy for those of limited sensitivity. Tumors of high sensitivity were those of embryonal origin, such as seminoma; primitive tumors of unknown origin, such as Wilm's tumor of the kidney; some tumors of the thyroid, salivary glands and nasal accessory sinuses, and tumors of reticulo-endothelial origin, such as lymphosarcoma, thymoma, Ewing's tumor and vascular endothelioma. For highly sensitive tumors, x-ray radiation was always the method of choice. There were four methods of palliation: (1) localized therapy for single sensitive deposits when more foci were present; (2) a growth-restraint technic for resistant tumors; (3) a "chasing technic" (individual treatment of a series of secondaries as they appeared) for secondaries following radical operation for cancer of the breast; (4) symptomatic palliative therapy.

Dr. N. S. Finzi said that in the technic now being followed by Dr. W. M. Levin at St. Bartholomew's Hospital the whole of the trunk was irradiated for some very sensitive deposits, and some striking results were occasionally secured. A number of the patients had now lived five years after treatment of generalized deposits of various radiosensitive tumors. It must not be supposed that there was any high proportion of cures in metastatic cases, but cures did occur.

Electrically Induced Convulsions

Electrically induced convulsions were discussed at the Section of Psychiatry of the Royal Society of Medicine. Dr. Grey Walter read a paper by himself, F. L. Golla and G. Fleming, from the Burden Neurological Institute. He said that during operations in which the brain was exposed a current of from 5 to 10 milliamperes evoked a response but that a hundred times that strength would have to be applied through the scalp. The ordinary 50 cycle alternating current from the mains provided an adequate stimulus that seemed to do no damage. If the first shock failed to produce a major seizure a second might succeed. The electromyographic record was much the same as the records obtained in spontaneous and metrazol convulsions.

Dr. Fleming added some details from the clinical side. At first sight electrically induced convulsions appeared to resemble epilepsy, but there was one important difference: the shock was followed by an immediate start or convulsive movement in all four extremities and then the tonic followed by the clonic phases of the epileptic convulsions occurred. The great objection to metrazol therapy was the latent period before the evocation of the fit, during which the patient was in a condition of intense terror. In the electrically induced seizure there was complete amnesia from the moment of the shock to the end of the convulsions. Again, the intense clonus of the metrazol fit was never observed. Of curative effects he preferred to say nothing at present. But just as with metrazol, some marvelous recoveries had been observed, although the time had not arrived for any assessment of value.

Dr. W. H. Shepley gave his experience in fifty cases treated. The conditions included schizophrenia, agitated melancholia, recurrent mania and hysteria. Some of the patients who had remained well on a maintenance dose (fortnightly) of metrazol showed the same response to electrical therapy. Advantages were removal of anticipatory fear and absence of after-symptoms such as vomiting, confusion and excitement.

Dr. C. R. Birnie took a skeptical view. He objected to the use of the term "therapy" for what was only an interesting piece of research. When metrazol therapy was brought forward at the same section he was one of the few who sounded a note of warning, which had been justified by the recent careful work done in America. An expert committee considered a large number of cases from the point of view of recovery and found that the results were no better than the normal remission rate. This was what psychiatrists might expect. The psychoses which they tried to treat were complicated by the reaction of the personality to the environment. They probably represented the attempt of a failing organism to make an adaptation which must be imperfect. The inhibitions, stupor and depression in many types of schizophrenia were attempts by nature to repress certain unconscious urges with which consciousness was unable to deal. The convulsive treatment released these urges, with which consciousness was no better able to deal than before the treatment.

War Wounds and Micro-Organisms

Levaditi and his collaborators, relying on observations during the war of 1914-1918, emphasize the frequency of war wound infections by anaerobic germs. He compares the results obtained twenty-five years ago with those of wounds in the present war. In an investigation of all species of micro-organisms found in wounds made by him in the army zone and in the hospitals evacuated for war purposes, 317 samples were taken. The results of this study were presented to the medical academy. Present observations, he said, do not differ much from those taken twenty-five years ago. Thirty-two per cent of the wounds harbored three kinds of micro-organisms, nineteen a single species, nineteen others four species, and twenty-three two, five or six species. Seven were sterile. The species most generally observed were staphylococci (85 per cent), Friedländer's bacillus, *Clostridium welchii*, streptococci, the coli group, the enterococcus and *Bacillus pyocyaneus*. The streptococci showed an increase from 19 per cent in 1917 to 58 per cent in the present count.

The treatment of these infections was improved by the discovery of the azo derivatives, administered orally and in the dressings or by the two methods combined. The intravenous injection of 0.15 Gm. every other day of neoarsphenamine had induced, he said, a more active process of cicatrization. However, it had no noteworthy effect on the microbial curves.

Levaditi isolated twelve stocks of streptococci in the pure state. They were all facultative anaerobes and generally of feeble virulence. Strong doses of p-aminophenylsulfamides applied in situ, in powder form or in glycerin, have had a remarkable prophylactic effect, confirmed by Perrin Long, of Johns Hopkins University. This drug constitutes both a local remedy and a general chemotherapy. It has no direct effect on the germ itself. The results obtained depend on individual resistance.

Knee Sprains

Leriche, speaking before the Academy of Surgeons, stated that knee sprains besides constituting "mechanisms, lesions or clinical aspects" were also often nervous phenomena, an accumulation of vasomotor reactions offering a characteristic clinical picture, without rupture of the ligaments or bone wrenches. Mondor also sought to define knee sprains. Are they simply torsions of the sensitive ends of the ligaments, developing the clinical appearance of edema, inflammation, hydrarthrosis, pain and functional inability or are they anatomic lesions of the ligaments? One does not always find, he said, in the course of primary interventions in knee sprains the classic lacerations of the ligaments. On the other hand, in twenty-eight cases he had observed seven wrenchings away of the spine of the tibia. In a woman aged 32, who had suffered a lesion through the torsion of the coxofemoral joints and who presented the clinical picture of a knee sprain, namely inward swelling, ecchymosis, local inflammation and after that lateral movements, a careful examination of the lesions disclosed a laceration of the patellar extremity and accompanying lesions; in short, a wide transverse injury of from 6 to 7 cm. These lesions were repaired by means of sutures and a reconstitution of the levels, and the limb was placed in a cast. Three years has elapsed, and recovery remains perfect with no functional disorders or joint looseness or osteomas.

This case did not exclude the possibility of concomitant nervous lesions, as Mauelaire pointed out. The good results obtained from cocaineizations of knee sprains support Leriche's emphasis on the part nervous lesions play in the entirety of symptoms provoked by the knee sprain. Schwartz thought that hemarthrosis which succeeds traumas immediately and the ecchymosis which accompanies them demonstrate tissue lesion and cannot be solely attributed to ganglionic fluxions.

Surgery of the Sympathetic Nerve

In the meeting of the Académie de chirurgie, January 3, the discussion centered round the innervation of the sympathetic nerve. Luzuy reported two almost identical cases of a seton wound in the forearm made by a bullet in which neither the bones nor the large nerve trunks were injured but which caused a complete insensibility of the arm with contraction of the hand and fist that resisted restoration. He diagnosed the condition as one of vasomotor disturbances and decided to operate on the stellate ganglion. A single penetration of the needle brought on Horner's syndrome, justifying the conclusion that a lesion of the sympathetic nervous system was involved. The infiltration of the ganglion promptly restored the contraction and the ischemic disturbances. Ameline thought that perhaps only a traumatic disturbance of the muscular tonus was implicated, the result of hypertonia, in which the "communicating branches" had been paralyzed and that it itself was under the influence of the stellate infiltration.

Welti and Wentz observed Raynaud's syndrome in a woman or, as they designated it, "circulatory disturbances of an ischemic type with digital eschars recalling Raynaud's disease." The left leg was amputated. When ulcerations developed on the stump, three cocaineizations of the lumbar plexus were tried, without success. Finally the thigh had to be removed. An eschar formed on the left hand. The ablation of the left stellate ganglion normalized conditions at this point. When ischemia and trophic disorders appeared in the right hand,

stelletomy was performed on this side with an ample perihumeral sympathectomy. On the day of the operation all ischemic symptoms disappeared. Welti and Wentz conclude that stelletomy and the enervation of the sympathetic nerve give good results, provided the operation is done on an ample scale. In one of Ameline's cases enervation was insufficient to maintain improvement for more than six months, probably because the enervation had not been sufficiently extensive.

Pierre Dival reported a case in which resection of the sympathetic nerve of the inferior mesenteric and hypogastric plexus was performed on a boy aged 9 presenting a true giant colon. The megacolon healed but left lesions on the wall of the colon. An intestinal occlusion supervened and an artificial anus had to be made on the right colon and afterward a hemicolectomy in the left side. Dival reported the boy in good health but with two colonic fistulas remaining to heal. According to Thierry de Martel, the role of the sympathetic nerve in organic disorders is to alter functional activity. Secondary lesions that result can be corrected, but the improvement may only too often be temporary.

BERLIN

Dietary Kitchens in Berlin

The first so-called ambulatory dietary kitchen has been instituted in Berlin; that is, a station where those in need of special diets can secure noonday and evening meals on medical certification. These kitchens are directed by a governmentally recognized dietetic assistant and supervised medically by the Organization for the Nutrition of the Sick. Patients entitled to this service are either employed or for other reasons are not in the position to make their necessary dietary arrangements. All kinds of diet can be prepared. The noonday meal costs 0.7 mark (28 cents) the evening meal 0.6 mark (24 cents). For more expensive diets an additional charge of 0.25 mark (10 cents) may be made. These dietary kitchens, of which two more are in preparation, are organized by an association of German women in conjunction with the public welfare division of the national socialist party.

Curbing Accidents Due to Drunkenness

Himmeler, chief of German police and head of the SS (schutzstaffeln) under nazism, recently promulgated the following order: Because of the large number of traffic accidents due to drunkenness, intoxicated persons endangering traffic are to be arrested and kept in custody for as many as twenty-four hours. Automobile drivers are to be deprived of driving licenses for a certain length of time. Drivers of other vehicles and bicycle riders can be deprived of their vehicles for two weeks. If such persons have caused an accident and conducted themselves unworthily or if they are habitual drinkers they may be kept for four weeks under police control. The same penalty applies to tavernkeepers if they serve alcoholic beverages to persons already intoxicated. Habitual drinkers whose vice affects the welfare of their dependents must regularly remit to them a part of their income. A vigorous attitude should be assumed in determining what constitutes alcoholic excess in individual cases.

The police department in Memel has ordered that all persons given to immoderate drinking be held in custody until the beginning of the next workday. Before being released, they are to be photographed. Their photographs together with their names are to be publicly displayed for a week. Taverns selling alcohol to drunken persons may be closed by the police.

Vaccines Against Dysentery

True bacillary dysentery (Shiga-Kruse) is rare in central Europe. In 1938 it was imported by migrating workers into Mecklenburg, in northern Germany, and had a 12 per cent

mortality rate. Preventive measures against bacillary dysentery have been inadequate. Recently Prof. R. Otto, director of the Institute for Experimental Therapy at Frankfurt on the Main (founded by Ehrlich and then directed by Kolle), reported on the use of his vaccine in Flexner's dysentery. He was able to curb an epidemic affecting 3,500 men at a military training post. Civilians living in the vicinity who were not vaccinated caught the disease and some died of it. Results like these have not been secured in the Shiga-Kruse dysentery. For this reason the statements of Prof. R. Prigge, a member of the same institute, before the Senckenbergische Naturforschende Gesellschaft, are of great interest. Prigge is known especially for his studies of diphtheria vaccines. In 1937 he announced his dysentery vaccine, which consists of a mixture of bacterial exotoxin with greater neural effects and endotoxin with special action on the intestine. The preparation is now in process of manufacture and is to be ready in the spring. In animal experimentation, excellent results were attained. The first clinical observations also are favorable but require extensive confirmation.

Effects of Seasons and Weather on Influenza

According to Prof. J. Wätjen, of the University of Halle, who investigated the effects of seasons and weather on influenza, there were found at necropsy during the months of February, March and April, after the severe influenza epidemic of the winter of 1936-1937, influenza bacilli in the bronchioles of about 33 per cent of the cases. These investigations were continued for another year until April 1938. Of the 1,370 sections 615, or 45 per cent, were examined bacteriologically. In 181, or 20.4 per cent, bacteria were discovered and in 434, or 70.6 per cent, none. The positive bacteriologic reactions fluctuated markedly in the individual months. A sort of spring peak was recorded from April to June 1937 and a winter peak during December 1937 and January 1938. Only during these two peak periods were also cases of localized pneumonia observed that resembled influenzal pneumonia. The spring peak of 1937 could be connected with the preceding winter epidemic; the increase of positive cases within the winter peak might have been due to the environmental factors. The official meteorologic indications were entered daily and monthly on the records, together with the positive and negative bacillary observations. In consequence, accumulations of positive observations were noted whenever the temperature fell to arctic frigidity. The mere invasion, however, of cold and warm air waves clearly was not sufficient to induce a regular occurrence of positive bacilli. Humidity, wind direction, sunshine and cloudiness exercised no effect. The winter peak of cases is regarded as an accumulation of influenza bacilli incidental to the season. This may be due to the tendency to catch cold when the weather is cold and wet. In spite of an increase of influenza bacilli in the bronchioles, contrary to expectations, no serious epidemic of influenza occurred in the winter of 1937-1938. This proves, according to Wätjen, that the presence of influenza bacilli alone is insufficient, even after penetration, to cause an influenza infection; other factors need to be present to produce influenza.

Personal

Prof Max Borst, professor of pathologic anatomy in Munich, celebrated his seventieth birthday Nov. 19, 1939. He was born in Würzburg and as a pupil of the pathologist Eduard von Rindfleisch laid the foundation of his career there. His excellent contributions, especially in the fields of inflammatory diseases and malignant tumors, soon paved the way for a distinguished academic career, which no doubt was aided by a natural eloquence and the ability of vivid presentation. He was called to Cologne in 1905, to Göttingen in the same year

and to Würzburg in 1906. In 1910 he succeeded von Bollinger in Munich. The new institute promised him at the time was not constructed until much later but is now one of the finest in the world. Borst is the author of a number of books. In 1902 he published the "Atlas of Malignant Tumors" in two volumes, "General Pathology of Malignant Tumors" in 1924 and the chapters on "Pathologic Growth" and "True Tumors" in Aschoff's textbook, which were constantly revised to keep abreast of research. Borst has been president of the state scientific commission for cancer control in Germany. He is not likely to resign during the progress of the war.

Deaths

Prof. Erhard Riecke, formerly professor of dermatology in Göttingen, died in Leipzig at the age of 71 (THE JOURNAL Oct. 14, 1939, p. 1502).

AUSTRALIA

The Law Against Abortion

Following the unexplained disappearance of several women during the last two years, the Queensland government continues to tighten the law relating to abortion. The new medical act, gazetted last month, compels practitioners to report immediately both to the police and to the director general of health any case of attempted criminal abortion or any suggestive circumstances. Members of the profession have criticized the act contending that, as it has not attacked the root of the problem, it cannot reduce the primary evil and that, by encouraging a serious breach of confidence between patient and physician, it will serve only to force the existing evil further into obscurity and unskilled hands. Now in an amendment to the health act further wide powers have been given to the police to search for missing women and those suspected of obtaining miscarriage. With or without a warrant from a justice of the peace, police may enter and search any suspected place without even so much as stating the grounds for "reasonable suspicion" and seize as evidence any object that might be used for procuring miscarriage.

Education in Mothercraft

The Mothercraft Association of Queensland in conjunction with the Queensland Nutrition Council has developed an organization whereby a series of lectures and demonstrations in all the wider aspects of mothercraft and homecraft are given annually not only to expectant mothers and young married women but also to girls intending to make homecraft their career. The course is organized in five sections: mothercraft, home nutrition, housecraft, child management and home first aid and home nursing. Each section comprises ten lectures and ten practical demonstrations. The lectures are given by leading medical men and others expert in their particular sphere. The course is excellent and popular. It shows a welcome advance on the teaching of mothercraft as it figures in the syllabus of some secondary schools and evening colleges, merged with many other domestic subjects of doubtful popularity. The Mothercraft Association encourages young girls to take the course, with a view to becoming trained workers in this field, and so able to take over the management of any home at a moment's notice in the event of a mother suddenly being taken ill or wishing to have a holiday away from her family. This idea is being readily accepted in Queensland. Since the outbreak of war, the association has arranged a further series of lectures dealing with a number of subjects related to emergency conditions, including mass feeding, care of large numbers of children in reception areas and substitution food values.

Medical Saga of the Air

For a brief period last week a new headline vied with the war news for the front page of Australian newspapers. A "flying doctor" and his pilot were reported missing somewhere in central Australia. Three days after they had set out from Cloncurry the plane was located, and the doctor and his pilot have now been rescued by a land party. That a flying doctor's plane has been forced down somewhere in uninhabited countryside is nothing new to these men, whose "practices" are lonely spinifex desert and rocky ranges. In eleven years of service, Australia has come to take the saga of the flying doctors somewhat for granted. Today more than 1,000,000 square miles and more than 3,000 people are served by the six medical men whose wings carry them on a 400 mile radius from Port Hedland, Cloncurry, Broken Hill, Kalgoorlie, Wyndham and Alice Springs. Last year, and the Alice Springs station was then barely established, the flying doctors flew nearly 100,000 miles. From the 600 pedal wireless stations scattered through lonely Australian outposts, and the receiving sets at the bases, came 37,554 calls for help for medical advice. Dr. Alberry, flying doctor of the Cloncurry base, who was reported missing last week, has himself circled the earth six times in milage on his flights to aid outback people.

RISK LIVES FOR PATIENTS

To land where there is no landing ground; to risk his life to reach a patient; to go where no white man has gone before, is nothing new to the doctors of the flying medical service. That is the flying doctor's job. So are all the other hazards that come their way. There have been times when the wing of a plane has formed the roof of their surgery; when, forced down in unknown territory, one or other had had to use all his skill to save his own life and the life of his pilot until help came. It has taken eleven years to complete the structure that an Australian inland mission padre dreamt of in Cloncurry in 1928, and "Flynn of the Island," now moderator general of the Presbyterian church in Australia, has lived to see his dream come true. The cost of maintenance of the six bases alone is more than £25,000 a year. Of this the commonwealth and state governments contribute £9,000. The rest comes from trusts and private donations. Last year the flying doctor service became the Australian Aerial Medical Service. Thanks to the flying doctor and his plane, much of the loneliness, much of the terror has gone from Australia's outback today. They are covering the open spaces of our land with a mantle of medical safety.

Marriages

JOHN EDWARD HOPKINS, Stoney Creek, Ont., Canada, to Miss Celia Teresa Faulhaber, of Clinton, Mich., in February.

ROBLEY CURTIS ALLISON, Petersburg, Va., to Miss Grace Elizabeth Johnson, of Lenoir, N. C., January 20.

WILLIAM MEIER MOODY, Cincinnati, to Miss Patty Alfred, of Covington, Ky., in Lexington, Ky., January 20.

RICHARD RAYMOND SLUCHER, Buechel, Ky., to Miss Mary Emma Hood, of Louisville, in February.

WILLIAM DOTSON WELLS, Paris, Ky., to Miss Susan Ellen Musgrave, of Louisville, January 27.

WALTER E. DANIEL, Charlotte, N. C., to Miss Ada Perry Gibson, of Leesburg, Dec. 30, 1939.

HAROLD GARTNER, Valhalla, N. Y., to Miss Dorothy Mathon, of New York, January 7.

HENRY LEE, Roanoke, Va., to DR. ELIZABETH L. SAUNDERS, of Radford, Dec. 26, 1939.

JOHN R. HILL to Miss Anna Gertrude Griffin, both of Knoxville, Tenn., February 9.

RAY BICKERMAN, Peoria, Ill., to Miss Kathryn Louise Eckert in Chicago, February 3.

Deaths

Martin L. Stevens @ Asheville, N. C.; Baltimore Medical College, 1891; member of the House of Delegates of the American Medical Association in 1907, from 1923 to 1936 and in 1938-1939; past president of the Medical Society of the State of North Carolina and the North Carolina Tuberculosis Association; member of the American Clinical and Climatological Association; fellow of the American College of Physicians; member of the state board of medical examiners from 1914 to 1920; during the World War served as chief of the local medical advisory board; member of the board of directors of the North Carolina Sanatorium and the Western North Carolina Sanatorium; on the staffs of the Ambler Heights Sanatorium, St. Joseph's Hospital and Sunset Heights, Asheville, and Biltmore Hospital and Hillcroft Sanatorium, Biltmore; aged 75; died, January 20, of coronary occlusion.

Raynham Townshend, New Haven, Conn.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the Connecticut State Medical Society; fellow of the American College of Surgeons; at one time assistant in the anatomic laboratory and clinical assistant in surgery, Yale University School of Medicine; served during the World War; attending surgeon to the Hospital of St. Raphael; assistant attending surgeon to the New Haven Hospital; consulting surgeon to the Grace Hospital and New Haven Orphan Asylum; aged 61; died, January 31, of coronary artery disease.

Harry Adolph Davidson @ Louisville, Ky.; Hospital College of Medicine, Louisville, 1899; member of the House of Delegates of the American Medical Association in 1923 and 1926-1927; since 1923 trustee and later secretary of the board of trustees and formerly professor of gynecology and physiology at the University of Louisville School of Medicine; served during the World War; on the staffs of the City Hospital and the Norton Memorial Infirmary; aged 64; died, January 20.

Charles Andrew Ray, Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1887; member and past president of the West Virginia State Medical Association and the Kanawha Medical Society; fellow of the American College of Physicians; president of the court of Kanawha County; formerly editor and on the editorial staff of the *West Virginia Medical Journal*; aged 75; medical director of the Kanawha Valley Hospital; died, January 21.

John Henry Bennett @ York, Pa.; University of Maryland School of Medicine, Baltimore, 1892; Jefferson Medical College of Philadelphia, 1893; member of the Radiological Society of North America; at one time city health officer and registrar of vital statistics; formerly member of the board of directors in the city school district; served during the World War; aged 67; on the staff of the West Side Sanitarium, where he died, January 4.

David Walker Basham @ Wichita, Kan.; Kansas City Medical College, 1884; University of the City of New York Medical Department, 1892; member of the Western Surgical Association; fellow of the American College of Surgeons; past president of the Sedgwick County Medical Society; on the staffs of the Wesley Hospital, Sedgwick County Hospital and the St. Francis Hospital; aged 85; died, January 17, of coronary occlusion.

Daniel George Monaghan @ Denver; Denver and Gross College of Medicine, 1903; member of the American Academy of Ophthalmology and Otolaryngology; served during the World War; aged 65; consultant on the staff of the National Jewish Hospital; past president of the staff and later served on the advisory board of St. Joseph's Hospital, where he died, January 17, of atrophic cirrhosis of the liver and arteriosclerosis.

Sambola Jones Couvillon, Moreauville, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1904; member of the Louisiana State Medical Society; parish coroner; for many years member of the parish school board; member of the state board of health; formerly mayor of Moreauville; past president and secretary of the Avoyelles Parish Medical Society; aged 60; died, January 21, in the Touro Infirmary, New Orleans.

John Joseph Cloonan, Stamford, Conn.; College of Physicians and Surgeons, Baltimore, 1897; member of the Connecticut State Medical Society; fellow of the American College of Surgeons; surgeon to Stamford Hospital; consultant to St. Vincent's Hospital, Bridgeport; for many years member of the board of education; at one time bank president; aged 69; died, January 28, of cardiovascular renal disease.

Amos Solon Wheelock @ Goodrich, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; past president of the Genesee County Medical Society; fellow of the American College of Surgeons; for many years member of the school board; surgeon to the Goodrich General Hospital; aged 78; died, January 22, when the automobile in which he was driving was struck by a train.

Manuel Diaz-Garcia @ San Juan, P. R.; Temple University School of Medicine, Philadelphia, 1916; fellow of the American College of Surgeons; medical director of the Clinica Diaz Garcia; consulting surgeon to the Hospital Mimiya, Santurce, Capital City Hospitals, San Juan, and the Municipal Hospital, Rio Piedras; aged 45; died, January 26.

Lorenzo Linn Zimmer, Detroit; Detroit College of Medicine, 1903; member of the Michigan State Medical Society; fellow of the American College of Surgeons; consulting gynecologist to the Receiving Hospital and St. Mary's Hospital; aged 60; died, January 22, in the Providence Hospital of appendicitis.

Clyde Allen Lown, Grand Ledge, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1904; member of the Michigan State Medical Society; aged 69; died, January 20, in the Edward W. Sparrow Hospital, Lansing, of intestinal obstruction, hypertension and arteriosclerosis.

L. Leopold Moser, Jamaica, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1919; member of the Medical Society of the State of New York; on the staff of the Jamaica Hospital; aged 47; died, Dec. 20, 1939, in the Jamaica Hospital of coronary thrombosis.

Charles Clifton Buchanan, Hattiesburg, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1909; member of the Mississippi State Medical Association; served during the World War; aged 52; died, January 22, in the Methodist Hospital of bronchopneumonia.

Edward A. Mattoon, Sapulpa, Okla.; Jefferson Medical College of Philadelphia, 1875; at one time superintendent of the Denver and Rio Grande Western Railroad Hospital, Salida, Colo., and the Okmulgee (Okla.) City Hospital; aged 91; died, Dec. 24, 1939, of a fracture of the hip.

Charles Nash Dawson, Black Earth, Wis.; Washington University School of Medicine, St. Louis, 1925; member of the State Medical Society of Wisconsin; served during the World War; aged 41; died, Dec. 26, 1939, in Beloit of intestinal hemorrhage and cirrhosis of the liver.

Walter Clark Montgomery, New York; Columbia University College of Physicians and Surgeons, New York, 1900; formerly assistant professor of clinical surgery, Cornell University Medical College; served during the World War; aged 61; died, January 15, of heart disease.

William Shelby Sanders, Troy, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; member of the Medical Association of the State of Alabama; formerly physician to the Troy State Teachers College; aged 71; died, January 13, of coronary thrombosis.

Frederick Cook, Seattle; Northwestern University Medical School, Chicago, 1903; member of the Washington State Medical Association; aged 61; died, January 2, in the Western State Hospital, Fort Steilacoom, Wash., of bilateral bronchopneumonia and diabetes mellitus.

Thomas O. Kirkpatrick, Lowndesville, S. C.; Tennessee Medical College, Knoxville, 1899; member of the South Carolina Medical Association; past president of the Abbeville County Medical Society; aged 71; died, January 19, of multiple sclerosis and bronchopneumonia.

General Sherman Wilson, Fortuna, Mo.; Barnes Medical College, St. Louis, 1899 and 1901; member of the Missouri State Medical Association; past president and secretary of the Moniteau County Medical Society; aged 64; died, January 7, of coronary thrombosis.

James Clarence Sartor, Rayville, La.; University of Louisville (Ky.) Medical Department, 1909; member of the Louisiana State Medical Society; member of the state board of health; served during the World War; aged 57; died, January 4, of coronary occlusion.

Ernest H. Bohland @ St. Paul; Medical Department of Hamline University, Minneapolis, 1903; on the staffs of St. Luke's Hospital, St. Joseph's Hospital, Charles T. Miller Hospital and Children's Hospital; aged 65; died, January 10, of acute endocarditis.

Roy Calvin Kitchell @ Sullivan, Mo.; Chicago Medical School, 1922; served during the World War; aged 48; died, January 4, in the Veterans Administration Facility, Jefferson Barracks, of peritonitis following an operation for appendicitis.

Horace Plummer Wilson @ Whittier, Calif.; Northwestern University Medical School, Chicago, 1896; fellow of the American College of Surgeons; served during the World War; aged 68; died in December 1939 of coronary heart disease.

Henry J. Off, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1896; since 1939 emeritus professor of otology at the Temple University School of Medicine; aged 65; died, January 28, of coronary infarct.

William Brewer @ Woodbury, N. J.; Jefferson Medical College of Philadelphia, 1896; past president of the Gloucester County Medical Society; owner of a hospital bearing his name; aged 74; died, January 28, of carcinoma of the liver.

Cary Stewart Wilson, Soso, Miss.; Memphis (Tenn.) Hospital Medical College, 1909; member of the Mississippi State Medical Association; aged 54; died, January 3, in a hospital at Laurel of hemorrhage due to gastric ulcer.

Oluf F. Carlson, Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1897; aged 74; died, January 23, in the Cook Memorial Hospital of cerebral thrombosis and lobar pneumonia.

Samuel Richard Volpe, New York; Cornell University Medical College, New York, 1936; resident physician to the Bellevue Hospital; aged 28; was found dead, January 23, of hanging and self-incised wounds of the wrists.

C. V. Arthur Weichelt, Barrington, Ill.; Jenner Medical College, Chicago, 1900; served during the World War; aged 70; died, January 4, in the Veterans Administration Facility, North Chicago, of cerebral arteriosclerosis.

Philip Doddridge Lipscomb @ Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1900; aged 69; died, January 4, of injuries received when he was struck by an automobile while crossing the street.

James Oscar Wickerham, Rockford, Ohio; Starling Medical College, Columbus, 1897; served during the World War; aged 75; died, January 14, in a hospital at Van Wert of a fracture of the hip received in a fall.

James G. MacGregor, Boyne City, Mich.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1895; member of the Michigan State Medical Society; aged 77; died, January 16, of cerebral hemorrhage.

Frederick Henry Brown @ Billings, Mo.; Barnes Medical College, St. Louis, 1899; served during the World War; aged 63; died, January 4, in the Springfield (Mo.) Baptist Hospital of carcinoma of the stomach.

Henry Clermont Miller, Bradenton, Fla.; Hahnemann Medical College and Hospital, Chicago, 1898; served during the World War; aged 69; died, January 9, of arteriosclerosis and hypertrophy of the prostate.

Albert William Nelson @ Battle Creek, Mich.; American Medical Missionary College, Chicago, 1903; fellow of the American College of Physicians; aged 61; died, January 5, of cerebral hemorrhage.

Thomas C. W. Ellis, Amite, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1891; at one time health officer of Tangipahoa Parish; aged 71; died, January 20, of angina pectoris.

Chester James Teass @ San Luis Obispo, Calif.; Cooper Medical College, San Francisco, 1897; fellow of the American College of Surgeons; aged 65; died, Dec. 23, 1939, of carcinoma of the esophagus.

James Erwan Hardaway, Lynn, Ark. (licensed in Arkansas in 1903); member of the Arkansas Medical Society; aged 67; died, January 4, in a hospital at Batesville of myocarditis and chronic nephritis.

Lawrence Anthony Zinsmeister, Sprout, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; aged 60; died, January 12, in the Memorial Hospital, Cumberland, Md., of heart disease.

James Harrison Rachels, Danville, Ill.; Meharry Medical College, Nashville, Tenn., 1908; aged 60; died, January 16, in St. Elizabeth Hospital of a ruptured esophagus resulting from hiccoughs.

Peter Arthur Schulberg, Durand, Wis.; University of Illinois College of Medicine, Chicago, 1914; aged 49; died, Dec. 29, 1939, in Butte, Mont., of chronic nephritis and cerebral hemorrhage.

Charles Brentano Wagner, Chicago; Chicago Medical College, 1888; on the staff of the Evangelical Deaconess Hospital; aged 74; died, January 18, in the Illinois Masonic Hospital of pneumonia.

Judge B. Pittman, Crenshaw, Miss.; Louisville (Ky.) Medical College, 1889; aged 72; died, January 21, in the Methodist Hospital, Memphis, Tenn., of coronary sclerosis and hemiplegia.

Augustus S. Warner @ Chicago; Northwestern University Medical School, Chicago, 1895; aged 71; died, January 18, in the West Suburban Hospital, Oak Park, Ill., of coronary thrombosis.

J. Lyman Hutchinson, Tacoma, Wash.; University of Buffalo School of Medicine, 1901; member of the Washington State Medical Association; aged 62; died, January 6, of coronary occlusion.

Theodore W. Singer, Louisville, Ky.; Cleveland Medical College, 1853; veteran of the Civil and Spanish-American wars; at one time deputy coroner; aged 104; died, January 3, of pneumonia.

John Milton Ryall Jr., Braddock, Pa.; Temple University School of Medicine, Philadelphia, 1937; aged 30; resident physician to the Braddock General Hospital; died, Dec. 14, 1939.

Isaac Lee Dowdey, Boaz, Ala.; Chattanooga Medical College, 1903; served during the World War; aged 66; died, January 24, in a hospital at Gadsden of cerebral hemorrhage.

Thomas R. Loer, Seattle; College of Physicians and Surgeons, Keokuk, Iowa, 1896; member of the Washington State Medical Association; aged 70; died, January 4, of pneumonia.

Charles Augustus Dodson, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1911; aged 65; died, January 8, of cerebral hemorrhage and hypertension.

Nathaniel L. Drunert, Truxton, Mo.; St. Louis College of Physicians and Surgeons, 1889; aged 77; was found dead, January 1, of diabetes mellitus and coronary artery disease.

Stonewall W. Johnson, Sullivan, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1887; formerly mayor and health officer; aged 76; died, January 19, of chronic nephritis.

Frank Cook, Springfield Lake, Ohio; Ohio State University College of Medicine, Columbus, 1931; aged 32; died, January 22, in the Edwin Shaw Sanatorium, Akron, of tuberculosis.

George Smith Williams, Syracuse, N. Y.; University of the City of New York Medical Department, 1890; aged 82; died, Dec. 5, 1939, of cerebral hemorrhage and arteriosclerosis.

Edward Kilbourne Roberts, Los Angeles; Yale University School of Medicine, New Haven, Conn., 1880; aged 82; died, January 15, in Simsbury, Conn., of chronic myocarditis.

Joseph Vincent Burns, Coaldale, Pa.; Jefferson Medical College of Philadelphia, 1915; served during the World War; aged 51; died, Dec. 31, 1939, of coronary thrombosis.

James W. De Jarnatt, Quitman, Ark.; University of Arkansas School of Medicine, Little Rock, Ark., 1905; aged 68; died, January 23, at Conway of cerebral hemorrhage.

George Francis Van Pelt @ Gordon, Ohio; Medical College of Ohio, Cincinnati, 1898; aged 70; died, January 24, in the Good Samaritan Hospital, Dayton, of pneumonia.

Grant Meyer, Marion, Kan.; Central Medical College of St. Joseph, Mo., 1896; member of the Kansas Medical Society; aged 71; died, Dec. 22, 1939, of cerebral hemorrhage.

William Hammond Ashby, Lewisport, Ky.; Hospital College of Medicine, Louisville, 1904; aged 62; was found dead, January 24, of a self-inflicted bullet wound.

Richard Douglas Keller, Greeneville, Tenn.; University of Tennessee Medical Department, Nashville, 1894; aged 71; died, January 3, of cerebral hemorrhage.

William Utteridge Cole, Columbus, Ohio; Starling Medical College, Columbus, 1890; aged 78; died, January 18, in the Grant Hospital of cardiorenal vascular disease.

Edwin Jacob Knerr, Wyoming, R. I.; Starling Medical College, Columbus, 1895; formerly senator; aged 69; died, January 15, of carcinoma of the rectum.

Claudius A. Gavin, New Port Richey, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1911; aged 55; died, January 6, of pulmonary tuberculosis.

William Andrew Gowing, Toledo, Ohio; Toledo Medical College, 1898; served during the World War; aged 68; died, January 17, of coronary thrombosis.

Clarence N. Ferguson, Chapel Hill, Tenn.; University of Tennessee Medical Department, Nashville, 1891; aged 71; died, January 13, of cerebral hemorrhage.

William Bowers Watts, Atlanta, Ga.; University of Georgia Medical Department, Augusta, 1889; aged 74; died, January 20, of cerebral hemorrhage.

Bureau of Investigation

POST OFFICE BANS A "PILE CURE"

"Pilocura," Alleged Brazilian Discovery, Is Declared a Fraud

A nostrum business operating from Washington, D. C., under the trade style "Pilocura Company, Inc.," has been declared fraudulent by the Post Office Department and debarred from the mails. Its principal promoters were a Paul W. DeLoe and his wife, Jane B. DeLoe.

These persons appeared at a hearing of the case which consumed an entire day. At the conclusion the DeLoes' counsel obtained permission to submit a brief, to which Hon. Vincent M. Miles, Solicitor for the Post Office Department, gave due consideration before recommending to the United States Postmaster that a fraud order be issued against the concern. Some of the information brought out by Judge Miles in his memorandum follows:

The business was started in 1912 by Mrs. DeLoe and incorporated in Delaware in 1932. At the time of the Post Office investigation Paul DeLoe was president and his wife Jane was secretary and treasurer. From 1932 on no newspaper advertising had been done, but since March 1938 circulars had been mailed to about 2,500 persons, whose names were purchased from a Chicago letter broker and a concern called M. Royds Company, of Kansas City, Mo. In this connection it is interesting to note that in October 1938 the M. Royds Company and its alias, Hugo Remedy Company, were debarred from the mails for conducting a fraudulent "pile cure" scheme and a "kidney and bladder cure." It is easy to believe that their "sucker lists" would be useful to the Pilocura concern.

The memorandum further brought out that not only were the DeLoes without medical training but also that no physicians, chemists or pharmacists were connected with the business. The treatment originally was sold over drug store counters as a liquid under the names "Safe Vegetable Compound" or "SVC." Jane DeLoe was said to have claimed that the product had come to her attention in 1902 or 1903 when she was visiting in Norfolk, Va. There, she said, her colored maid took something that a friend recommended for "piles" and in three days they were gone. So impressed was Mrs. DeLoe, she said, that she made another trip to Norfolk, where she learned that the preparation was sold by "a little German doctor" who told her he had bought it twenty-five years previously on a trip to Brazil. He claimed, she said, that its efficacy depended on a certain herb unknown in this country. Mrs. DeLoe related that she prevailed on him to sell her the formula for \$250 on the promise that she would not make it public during his lifetime.

Mrs. DeLoe described the "cure" as originally obtained by her maid as a bad-tasting, evil-smelling, sticky brown liquid, composed of seven ingredients and 25 per cent of alcohol. The mixture was known as "South American Herb Remedy." Mrs. DeLoe testified that after selling it in this form for a time through drug stores she had it analyzed by a "Dr. Kalusowski" (no such name appears in the American Medical Directory) and asked him to revise the formula so as to make it "really effective." On his advice she eliminated the alcohol and three of the ingredients, whose names she had forgotten, reduced the remaining constituents to tablet form and changed the name to "Pilocura." She added that she had not intended this title to mean "pile cure" but merely that it "struck her as a nice little name."

Advertising circulars introduced at the hearing contained not only the company's claims but a number of testimonials, to most of which only initials were signed. One inquirer received from the company a typewritten letter reading in part:

"During the past several years we have come up against a great number of desperate cases of piles, as the enclosed circular will indicate. If you will give PILOCURA a fair trial we believe you will be satisfied that an operation will be unnecessary. We are enclosing a letter which may also be of interest to you."

The Solicitor's memorandum reported that examination of the Pilocura tablets, prepared by Burroughs Bros. Mfg. Co., Baltimore, showed that each consisted essentially of large amounts of licorice and rhubarb, as well as some yerba santa and buck-

thorn (frangula). It was surmised that the yerba santa represented the "little known" Brazilian herb which the promoters of Pilocura played up as one of the ingredients. The DeLoes' only medical witness, named as a Dr. Howard Hume, testified that the yerba santa "is supposed to be an alterative and build up the general health" and "seems to be the most important thing" in the preparation. However, his testimony as to its effect on the human system placed it in the same class with the three other ingredients as a "mild laxative" and he was unable to explain how it allegedly affected the general health. The government's two medical experts testified that yerba santa was used principally as a flavoring ingredient in certain preparations and, except for such slight laxative effect as it might produce in connection with the other ingredients, it was therapeutically worthless as used in Pilocura.

The government's medical evidence showed further that the basic causes of hemorrhoids are many and varied and that frequently the conditions and their accompanying pains disappear without resort to medication. Also this evidence brought out that the only treatment that will replace or restore to normal the tissues in the rectal veins that have been damaged by chronic, recurrent hemorrhoidal attacks is either surgery or injection of sclerosing materials in and about the walls of the veins. Further expert testimony was presented to show that such treatments as Pilocura may irritate and aggravate the hemorrhoidal tissue instead of healing it.

In October 1938 it was reported that a "Dr. Jane B. Coates" was connected with the Pilocura Company in Washington. No record of her could be found in the American Medical Association's files, but in the Washington telephone book ("Summer-Fall 1937") there was listed a "Rev." Jane B. Coates. In the current issue of that directory ("Summer-Fall, 1939") "Rev." Jane B. Coates is shown at "1810 Ont. Pl. N.W.," which is the same address (and has the same telephone number) as is given for "Rev." Paul W. DeLoe, one of the Pilocura promoters. The Pilocura Company is not listed. One cannot help wondering whether "Dr." or "Rev." Jane B. Coates and Mrs. Jane B. DeLoe are not one and the same person.

All in all, the Solicitor found from the evidence presented that the Pilocura business was "a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises" and on his recommendation a fraud order debarring it from the mails was issued on March 24, 1939, against the concern under its several "Pilocura" designations and against the officers and agents as such.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Elco Cold Treatment.—Erie Laboratories, Cleveland. Composition: Approximately 2.8 grains of phenacetin and 0.7 grain of acetanilid per capsule. Misbranded because these drugs were declared in false amounts on bottle label and not declared at all on the carton as to presence and quantity.—[N. J. 30229; June 1939.]

Furmas.—Erie Laboratories, Cleveland. Composition: Essentially a mixture of magnesium hydroxide and carbonate, sodium and potassium carbonates and/or bicarbonates, a water-soluble red substance, peppermint oil and water. For acidosis, dyspepsia, functional stomach disorders, headaches, sleeplessness, nervousness, dizziness, etc. Fraudulent therapeutic claims.—[N. J. 30229; June 1939.]

Mrs. Bee Health Anodyne Capsules.—Erie Laboratories and Mrs. Bee Health Laboratories, Cleveland. Composition: Essentially phenacetin, aspirin and caffeine. For painful menstruation. Fraudulent therapeutic claims.—[N. J. 30229; June 1939.]

Mrs. Bee Hypo-Tonic Pills.—Erie Laboratories and Mrs. Bee Laboratories, Cleveland. Composition: Chiefly plant material, coated with sugar and iron oxide. Fraudulently represented as a system tonic and nerve sedative for rundown, irritable women.—[N. J. 30229; June 1939.]

Prescription 333.—Erie Laboratories, Cleveland. Composition: Essentially aspirin and sodium salicylate. Fraudulently represented as a prompt relief of pain caused by lumbago, neuralgia, gout, arthritis, sciatica, neuritis and swollen joints.—[N. J. 30229; June 1939.]

Correspondence

TREATMENT OF BITES OF RABID ANIMALS

To the Editor:—Permit me to refer again to the question of treatment of bites by rabid animals, which was covered under Queries and Minor Notes on page 1434 of THE JOURNAL, Oct. 7, 1939.

Since the Pasteur treatment is not 100 per cent effective, by reason of its inability to protect against more than one to three minimal infective doses or to develop the requisite degree of immunity in cases in which the incubation period is short, any other form of treatment which holds out any hope at all of exerting a preventive influence must be applied. The only other treatment at present available is the cautery, either actual, as in the days of Pasteur, or by nitric acid, as at present. The rationality of this procedure can be readily appreciated by a consideration of certain facts concerning virus invasions, particularly the invasion of rabies. Any one who has ever tried to stop a smallpox vaccination take by scrubbing with soap and water or even iodine will appreciate the need of a destructive agent—destructive alike to the tissues and to the still superficial virus. That the virus of rabies remains for a reasonable time in the wound and is not carried away rapidly by the lymphatics is an indisputable fact. The observations of McMaster and Hudack, referred to in the editor's answer to the correspondence and which reveal the speed with which particulate matter is carried away by the lymphatics, are not applicable to rabies. Any rabies virus which may be taken up by the lymphatics is for that very reason rendered *hors de combat*, since the evidence is that rabies virus so introduced is not effective. Rabies cannot be produced experimentally by introducing large quantities into milk, fed to susceptible animals. The disease is never produced by consuming the milk of rabid animals, although the virus, it is said, has been demonstrated in milk. I have inoculated a thousand minimal infective doses of fixed virus subcutaneously in rabbits without producing infection.

The port of entry of the rabies virus in nature is not the lymphatics or the blood stream but the nerves. It is by way of the nerve trunk that the virus travels from the smaller branches in the superficial tissues to the cord and brain. The rate of travel is slow, which accounts for the long incubation period of the disease. The reason for shorter incubation periods when the inoculation is near the brain is thus made clear. While it is true that experimental infection can be produced by intravenous inoculation, the doses are enormous relative to the natural method by an animal's bite, and the results of such inoculations are uncertain and irregular. There is no evidence that natural infection ever occurs by way of the blood stream. Animals survive experimental nerve inoculations when the nerve trunk central to the site of an inoculation is resected, while the resected nerves themselves are infective. It has also been shown that the portion of the spinal cord in connection with an infected nerve becomes infective before the rest of the central nervous system (Marie et al., 1927). Even the infectious quality of saliva is not due to any involvement of the salivary gland tissue but to the presence of neurons, which may occur as single cells or as ganglionic aggregations and which are seated just under the epithelium, the virus being set free from the neurons by abrasion of the epithelium (Topley and Wilson). The virus may spread centrifugally from the brain and be found in such nerves as the brachial and the sciatic (Nicolau and Galloway, 1928).

Not only does fuming nitric acid destroy both tissues and virus on the surface with which it comes in contact but the effect penetrates for a limited but appreciable depth. The contention that one cannot reach absolutely all corners which harbor virus and that for this reason cauterization is useless is without merit. The importance of dosage in relation to the chance of successful infection in all diseases is well known. The principle is of manifold importance in rabies, in which the vaccination treatment is capable of generating a resistance against only a limited amount of virus. It is therefore most essential that the specific treatment be aided by a reduction of the force it has to combat, and this aid is effectively given by thorough cauterization of the wound. Cauterized wounds heal readily, and considerations of scarring have no weight whatever. Indeed, a bite on the face, in which case cauterization is most likely to be withheld because of the fear of scarring, is precisely the one, above all others, which requires thorough treatment, for reasons previously referred to.

As between prompt and thorough cauterization and the Pasteur treatment, there is a question as to which used alone would be the more effective. In my opinion, if all the facts were known it would be found that cauterization is the more valuable. The various estimates of the percentage of successes of the vaccine treatment are subject to considerable modification, because of the many unknown factors which tend to swell the number of cases that should not be included in the series. These include such things as the amount of virus introduced (only one out of six persons develops rabies without treatment), injury of nerves, bites through clothing and the question of rabies in the dog. Everything considered, the omission of cauterization by a physician who knows these facts is a dubious performance.

TOXIC HEPATITIS AFTER CINCHOPHEN

To the Editor:—In the article "Toxic Hepatitis and Acute Yellow Atrophy Following Medication with a Cinchophen-Containing 'Cold Cure'" by Cyril M. MacBryde, which appeared in THE JOURNAL on January 27, the author states in his summary (p. 318) that he "was unable to find any previous reports of ulcers caused by cinchophen in the human being, although peptic ulcers have been so produced in experimental animals." Evidently our papers (Gastric Ulcers Associated with Cinchophen Poisoning: Report of an Instance with Consideration of the Possible Etiologic Relationship, *Am. J. Digest. Dis. & Nutrition* 1:29 [March] 1934; Cinchophen Poisoning: A Report of Seven Cases with Special Reference to a Rare Instance Complicated by Multiple Gastric Ulcers, *ibid.* 1:434 [Sept.] 1934) escaped the author's attention. Based on the original experimental work of Van Wagoner and Churchill (*Proc. Soc. Exper. Biol. & Med.* 28:581 [March] 1931; *Arch. Path.* 14:860 [Dec.] 1932), we suggested and discussed the probable relationship between cinchophen poisoning and the finding of gastric ulcers in a patient who had been under our observation. A careful search of the literature at that time revealed one other similar case reported by Reah (Cinchophen Poisoning, *Lancet* 2:504 [Sept. 3] 1932), but the possible relationship of peptic ulcers to cinchophen intoxication had received no consideration. Hence an abstract of Reah's case was included in our paper. In our summary we "suggested that a careful anamnesis in all peptic ulcer patients from the standpoint of cinchophen therapy might yield interesting data."

LEON BLOCH, M.D.

DAVID H. ROSENBERG, M.D.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DERMATITIS FROM SALT WATER BATHING

To the Editor:—In a camp situated on the Florida Keys I have observed that, after a group of men have been here for from four to eight weeks, 50 per cent develop a papulopustular dermatitis, which is localized mainly in the axilla, usually bilaterally and concomitant. There are no other signs or symptoms nor elevation of temperature. In this region it is commonly known as "salt water itch" and believed to be the result of constantly bathing with salt water and being exposed to the salt vapor laden air. Therapeutic attempts with calomine lotion, salicylic alcohol, ammoniated mercury and the like have been moderately successful in drying up the lesions. There have been but few cases of secondary infection. The problem is more one of prevention than of treatment, for in a camp of this kind a situation of this nature is detrimental to the morale of the men. Could you advise or refer me to the proper prevention of this dermatitis other than attempting to go over to fresh water bathing, which is unfortunately an unpractical solution in this locality?

Henry B. Dubins, M.D., Ramrod Key, Fla.

ANSWER.—Salt water alone does not commonly produce any irritation or infection. It is possible that some tropical plant or minute animal may cause such a dermatitis, with a low grade secondary infection. The best answer, of course, would be fresh water and soap, but it is realized that this is not practical on a Florida key. The use of a 75 per cent alcohol in saturated boric acid solution is suggested for routine use after bathing. It is possible that Burow's solution (aluminum acetate) in a dilution of 1:20 or 1:10 might also prove of help. Whether the protection obtained by having each individual go over his body with an oily solution, either olive oil, coconut oil or petrolatum, would be of benefit is a question. Perhaps the addition of boric acid to the protective solution or the use of boric ointment, applied previous to bathing, might also be helpful. Of course this is messy and may not appeal to the individuals concerned.

HERPES ZOSTER OF TRIGEMINAL NERVE

To the Editor:—About four years ago a patient, now 30 years of age, complained of pain in the right supra-orbital division of the fifth nerve which became increasingly severe, with a dull constant burning, varying only in intensity. The pain was present in the right frontal area of the scalp, with one area on the right parietotemporal region of the scalp, at which point there was a cutaneous lesion, diagnosed by a competent dermatologist as herpes. This lesion was excised, and the pathologic report indicated a chronic inflammatory process. There are herpetiform lesions on the right frontal area of the scalp also, which have appeared from time to time since the onset of pain. No sedatives give relief, not even morphine sulfate 1 grain (0.06 Gm.) when the pain is severe. Trichloroethylene and chloroform do not help. Roentgenograms have been taken of the teeth, revealing no impacted molars and clear sinuses. Stereoroentgenograms of the skull are normal, some calcification appearing in the right choroid plexus only. The encephalogram and results of spinal fluid examination, including reactions to the Wassermann and the pressure test, were normal. No drugs or combination of drugs completely remove the pain, which at present is more bearable than formerly. I have discussed this case with a neurosurgeon, who says that avulsion of the right supra-orbital nerve will completely rid the patient of this pain. How serious is avulsion of the supra-orbital nerve? The patient was told that it could be done with local anesthesia, yet he was advised to enter the hospital the night before the operation. This frightened him greatly, as it indicates a serious operation—to his mind. He was under the impression that he could walk in the same morning, go to the operating room, undergo the necessary surgical procedure and be at home in two or three days. Kindly advise me whether in your opinion avulsion of the supra-orbital nerve will rid the patient of his pain. How serious is this procedure? Is there any other treatment that can be advised in this case? The pain completely incapacitates the patient. What are the after-effects of avulsion of the supra-orbital nerve?

M.D., New York.

ANSWER.—The condition described is doubtless herpes zoster of the trigeminal nerve, manifest peripherally in the area of supply of the ophthalmic division of that nerve. The cause of such herpes is probably the same as that of herpes zoster in the spinal nerves; that is, a low grade, chronic, usually non-destructive inflammation on an unknown basis. Histologically the changes in the gasserian ganglion have been shown to be the same as those in the dorsal spinal ganglions, to which the gasserian ganglion is anatomically analogous. A causative virus has been postulated but never isolated. Such an affliction must

always be carefully differentiated from major trigeminal neuralgia, and when the herpes is in the ophthalmic division, as here, there is always the danger of vesicle formation with resultant scars in the cornea.

Avulsion of the supra-orbital nerve is a minor operation and may be accomplished easily under simple procaine hydrochloride anesthesia with a minimum of preoperative and postoperative hospitalization. A small incision through the eyebrow is the site of choice for the operation.

In this case avulsion of the supra-orbital nerve would probably give relief if the pain and herpes are entirely within the area of supply of that nerve. Such an operation is worth trying. But it must be remembered that the pain of herpes trigeminalis may be centered in the pons, so that even section of the posterior root will give no relief.

High voltage roentgen treatment of the gasserian ganglion has been suggested but is not noteworthy for its results, and avulsion of the nerve is the usual procedure.

After avulsion of the nerve, the area of supply will be anesthetic to light pain, light touch, heat and cold stimuli. After a few months, when the nerve has again grown out, sensation will be reestablished and the pain may or may not recur.

PAPAVERINE IN ASTHMA, ANGINA AND COLDS

To the Editor:—I should like to know whether papaverine is of any special value or of greater value than the usual drugs used in bronchial asthma, angina pectoris and head colds (in combination with codeine or, for instance, copavin-Lilly). Can papaverine be procured in one-half grain tablet form?

M.D., Iowa.

ANSWER.—Papaverine exerts a peripheral depressant action on the contractions and tonus of all kinds of smooth muscle. Its peripheral effect includes lowering of intestinal tonus, lowering of high blood pressure by vasodilatation and increase in coronary circulation. Primarily because of its effectiveness in spastic conditions of the gastrointestinal tract and other hypertonic conditions (biliary colic, bronchial spasm and in the diagnosis of pylorospasm), papaverine is included in New and Nonofficial Remedies. With less reason it has been tried in hypertension, angina pectoris, vomiting, gastric crises, asthma and whooping cough. Most authorities do not include papaverine as a remedy for the latter.

The successful use of the opiates in the treatment of common colds has been reported by H. S. Diehl (Medicinal Treatment of the Common Cold, *THE JOURNAL*, Dec. 23, 1933, p. 2042). Copavin is the proprietary name under which Eli Lilly & Co. markets under license of the University of Minnesota a mixture of codeine sulfate and papaverine hydrochloride one-fourth grain (0.016 Gm.) each. Since both of these ingredients are official in the U. S. Pharmacopeia XI and National Formulary VI, the Council on Pharmacy and Chemistry has failed to see the justification for a proprietary name or patent to control their combination, as the use of opium (Dover's powder) in the treatment of colds is not new.

Papaverine hydrochloride alone can be procured in tablets of any dosage when prescribed by a physician possessing a narcotic license. The average dose is stated as 1 grain (N. F. VI). Papaverine or codeine alone is relatively nontoxic in therapeutic doses, but together the presence of the former may potentiate the action of codeine (Possible Symptoms from Copavin, *Queries and Minor Notes*, *THE JOURNAL*, April 16, 1938, p. 1304).

EOSINOPHILIA AND SULFAPYRIDINE

To the Editor:—Two patients treated with sulfapyridine experienced an eosinophilia of from 8 to 10 per cent shortly afterward. They did not have this eosinophilia before sulfapyridine was started. Can the use at sulfapyridine explain the eosinophilia? Doses were about 100 grains (6.5 Gm.) a day.

Raymond H. Goodale, M.D., Worcester, Mass.

ANSWER.—There are no controlled published observations indicating that sulfapyridine may cause an eosinophilia in human beings. P. O. Hageman (*Proc. Soc. Exper. Biol. & Med.* 37:119 [Oct.] 1937) has noted that in mice which received azosulfamide (neoprontosil) over a period of two weeks, large numbers of eosinophil leukocytes were found in the bone marrow at necropsy. Kreutzmann and Carr (*ibid.* 38:19 [Feb.] 1938) noted that moderate doses of azosulfamide given to rabbits for a period of three weeks produce an increase in the stipple cells and eosinophil leukocytes in these experimental animals. Hence it is possible in the two cases in which an eosinophilia was noted in the course of the use of sulfapyridine that this change in the leukocytes was due to the administration of the drug.

ALLERGY TO VEGETABLE OILS

To the Editor:—One of my patients has proved hypersensitive to sesame oil, peanut oil, olive oil and most of the vegetable oils. Will you kindly advise what vehicle could be used to dilute the sesame oil, for instance, in order to desensitize this patient against it?

M.D., Texas.

ANSWER.—The query is rather indefinite, as it does not state how the oils were administered. These oils are, of course, used both by mouth or as a vehicle for administering medication intramuscularly. It is difficult to desensitize against an oil, although some work along this line has been done with the oil fraction of poison ivy, ragweed and burweed marsh elder.

In these cases dilute injections have been given with increasing doses for the purpose of raising the resistance of the patient. The results of such treatment are in dispute, with both favorable and unfavorable reports in the literature.

A more logical method would be to substitute some other edible oil for the one to which the patient is sensitive. In a paper entitled "Animal and Vegetable Fats and Oils," U. S. Dept. of Commerce Bureau of the Census, 1937, the following edible oils are listed, any one of which can be taken as a substitute for the one the patient cannot tolerate:

Cottonseed oil	Peanut oil	Coconut oil
Corn oil	Soybean oil	Olive, edible
Palm-kernel oil	Rapeseed oil	Palm oil
Sesame oil	Sunflower oil	Babassu oil
Oleo oil	Fish oils	Tallow, edible

There is also some question as to whether any one is really sensitive to any pure oil which is free from protein. Patients who are sensitive to materials which contain both an oil and a protein are sensitive to the protein fraction and not to the oily part; therefore if the oil is entirely free from protein it should give no symptoms whatever. In support of this is the paper read by Harry S. Bernton, M.D., Joseph R. Spies, Ph.D., and Henry Stevens, Ph.D., on the "Significance of Cottonseed Sensitiveness" before the American Association for the Study of Allergy in June 1939. They have definitely shown that patients are sensitive to cottonseed protein and not at all to cottonseed oil U. S. P. Contact dermatitis, however, may be due to the oily fraction of plants and other substances. The protein fractions may be responsible for bronchial asthma, allergic rhinitis, atopic dermatitis, migraine and other typical allergic conditions.

TRAUMA AND RETRODISPLACEMENT OF UTERUS

To the Editor:—A woman aged 25 was riding on July 31, 1938, in the rear seat of an automobile which was struck by another car from the rear. On the following day she complained of same headache, stiffness of her neck, and backache. There were also various minor bruises about both knees. Examination at that time showed some typical sprains of the muscles of the neck and of the trunk. The uterus, however, was displaced posteriorly but seemed to be normal in size, shape and consistency. The other adnexa appeared to be normal. There were bruises over both knees. The patient continued to complain of backache and in August 1939 the vaginal examination was approximately the same, that is a third degree retroversion which could not be corrected by palliative means. Could the accident have caused this retroversion? There is also a question as to whether or not a patient with a retroversion can become pregnant and if there is any scientific basis for a suggestion that spontaneous miscarriage would take place if she did become pregnant. It has been my experience that external trauma such as she sustained has no bearing whatever on the position of the female generative organs. Any information which you can give me with regard to this type of case will be appreciated.

M.D., Illinois.

ANSWER.—The question of retrodisplacement of the uterus following trauma is complicated and controversial. Spicer states that "traumatic displacements (of the uterus) may result from a fall, sudden jarring of the body, such as landing on the feet or buttocks, lifting heavy bodies, and blows over the lower abdomen." Adair says "It is also possible for a blow upon the back, or a fall upon the buttocks, to cause an acute retrodisplacement of a nonpregnant uterus, or of a pregnant uterus early in gestation. . . . It is also possible that a preexisting displacement may be aggravated by traumatic causes. . . ." Kessler states that there are two schools of thought concerning the relation between injury and uterine displacement. One flatly denies the relation and the other favors traumatic etiology in selected cases. Many authorities have apparently seen enough instances of retrodisplacement of the uterus following a severe fall to lead to the conclusion that forceful impact, such as falling on the back, may produce a bad retrodisplacement. For every such instance, however, there are many in which the patient gives a history of falling and has a retrodisplacement which is not ascribable to the injury. In almost all instances the exact relation seems difficult to prove.

Failure to conceive is rarely due to retroversion of the uterus alone. Authorities are not wholly in accord concerning the tendencies to spontaneous miscarriage in patients with retrodisplacement, but the consensus is that retrodisplacement of the uterus is a factor of some importance in the etiology of spontaneous abortion. IMMUNITY WITH TETANUS TOXOID

To the Editor:—There has been discussion from time to time here as to the advisability of using tetanus toxoid rather than tetanus antitoxin in industrial injury cases. It would be of enormous benefit to use the toxoid and immunize many of the waterfront employees, since many cases necessitating divided doses of the antitoxin due to sensitivity are seen. Would the protection against tetanus of persons immunized with toxoid and given another dose of the toxoid at the time of injury be as great as is afforded at the present time by the use of the tetanus antitoxin prophylactically?

M.D., California.

ANSWER.—In horses, tetanus toxoid produces a stable, effective and lasting immunity against tetanus. Two injections of 10 cc. each have been given at an interval of one month and a third injection of the same amount a year later. Resulting immunity has been found to last at least eight years. References are given by Gold, Harry: Active Immunization Against Tetanus, *Ann. Int. Med.* 13:768 (Nov.) 1939. The Paris correspondent of THE JOURNAL, Feb. 3, 1940, p. 424, refers to the work on horses by Ramon and Lemetayer.

Recent experiments by Gold again show that in human beings tetanus toxoid induces an active immune response, with the appearance of tetanus antitoxin in the blood. Gold injected 1 cc. of toxoid two or three times at intervals of one month. Another injection a year or so later raised the antitoxin content in the blood in four or six days to a protective level of 0.1 unit or more per cubic centimeter of serum. "One week after the 'repeat' dose, the antitoxin titer of an immunized subject is from two to fifty times greater than the titer produced by the injection of 1,500 units of tetanus antitoxin." It consequently appears to be established that in persons previously immunized with tetanus toxoid a new injection of toxoid will give better protection than the usual prophylactic injection of 1,500 antitoxin units. In occupations especially liable to traumatic tetanus, active immunization with toxoid for preventive purposes should receive serious consideration.

HEPARIN AND THROMBOSIS

To the Editor:—Have you any information as to the safety and dosage of heparin administration in the different types of thrombosis, and which heparin preparations can you recommend?

F. E. Prytek, M.D., Brooklyn.

ANSWER.—This question cannot be answered adequately in brief form. No physician should use heparin clinically until he is familiar with the literature on the subject. The highly purified material may be given by continuous intravenous infusion for days at a time. It decreases coagulation of the blood and does not do harm, apparently. To keep the clotting time of the blood at three times its normal value, Best and his co-workers employ a saline solution containing 1,000 units (10 mg.) of heparin in each hundred cubic centimeters of solution, which is allowed to run into the vein at the rate of about twenty-five drops a minute. Single intravenous injections are effective in ten minutes and decreased coagulation of the blood persists from one to three hours, depending on the amount injected. A good review article is Mason, M. F.: Heparin: A Review of Its History, Chemistry, Physiology and Clinical Applications, *Surgery* 5:451 (March), 618 (April) 1939. Other valuable articles are: Murray, G. D. W., and Best, C. H.: The Use of Heparin in Thrombosis, *Am. Surg.* 108:163 (Aug.) 1938. Murray, D. W. G., and Best, C. H.: Heparin and Thrombosis: The Present Situation, *THE JOURNAL*, Jan. 8, 1938, page 118. Round Table Discussion: Clinical Problems of Thrombosis, *Minnesota Med.* 23:1 (Jan., supp.) 1940.

QUERIES AND MINOR NOTES

913

INTRADERMAL AND SCRATCH TESTS IN CHILDREN
To the Editor:—With regard to the relative value of protein tests in cases of allergy: What is the value of scratch tests with individual proteins combined into related groups? Does the dilution of the individual proteins necessitated by combining them into groups interfere with the response to the scratch tests in view of the difficulty of interpretation of the wheal and the erythema as a response to the temporary occlusion of the capillaries of the skin at the site of injection when the scratch gives a similar experience using the intradermal test? With a preface limited to children, intradermal tests are difficult to carry out in the office and even in the hospital if one has any sensibility to the child's reaction to pain.

ANSWER.—Cutaneous testing with combined proteins, by either the scratch or the intradermal method, is not to be recommended. It is not nearly so accurate as testing with the individual proteins. With infants and young children, routine intradermal testing is recommended. It is best to do a routine set of scratch tests first and then a few intradermal tests with some of the more important allergens to which there has been no reaction by the scratch method. There can be no doubt that the intracutaneous method is much more delicate than the scratch method, and many significant reactions will be missed if the latter is used alone. This is particularly true for milk in infants and for house dust and feathers in older children, all of which may be important in causing allergic manifestations. No intracutaneous test should ever be done on an infant or child with any environmental allergen unless it has been preceded by a negative scratch test. The same holds for any food which has never been eaten or for any food which is known to have produced violent symptoms. If a food has been regularly eaten without having produced any violent symptoms, it is safe to do an intracutaneous test before having done a scratch test.

ALCOHOLIC INTOXICATION AND CEREBRAL CONCUSSION

To the Editor:—What basis, if any, is there for a statement such as "How difficult it is to distinguish accurately between outward manifestations of concussion and of intoxication is readily apparent from the following comparison of symptoms" (Prof. Lawrence Vold, College of Law, University of Nebraska, in "Laboratory Tests for Alcoholism in Motor Accidents Prosecutions," Nebraska Law Bull., vol. 17, 1938, No. 2). A long list of purported symptoms in common follows: On a previous page several authorities on brain injuries were cited, but I was unable to find any such statement in them. It is my impression that confusion could exist between punch drunkenness and intoxication, but punch drunkenness is a result of cumulative blows to the head over a period of years and not due to any single hard blow. I am familiar with the answer to a similar question in The Journal, Aug. 20, 1938, but would like a more specific reply, wherein the claim was made that the accused was "punch drunk," "foul on his feet" and knew nothing until he came to several hours later to find himself peeing back and forth behind the bars of a cell. The author leads up to this assertion by repeated statements as to the great similarity between concussion (it had to be simple in this case, as the accused had evidently "recovered" by the next day) and intoxication from alcohol. The result of 0.23 per cent alcohol from a laboratory test was dismissed as a "terrible error."

ANSWER.—By "cerebral concussion" is meant a state of partial or complete unconsciousness plus a widespread paralysis of cerebral function, both of which come on immediately after trauma to the head. A knockout blow delivered in a prize fight is a typical example of how concussion may be produced. In addition to the unconsciousness, which may be for a few seconds or minutes, the respirations may become shallow; the pulse weak and slow; the blood pressure low; the face pale and the pulse weak. The latter signs are dependent on the severity of the concussion; the more severe the concussion, the more frequent will these signs be. Simple cerebral concussion rarely, if ever, simulates alcoholic intoxication. There may be difficulty in a patient who has been drinking and who then develops a cerebral concussion. This occurs quite frequently. Even in such a case the differentiation should not be a problem. In simple concussion of the brain without fracture or compression there is usually some disturbance of consciousness, ranging from "seeing stars" to a temporary loss of consciousness. Severe or prolonged stupor or deep coma is not characteristic of simple concussion. These indicate much more grave brain damage or injury. Here deep sleep from alcohol can be easily differentiated from a deep coma the result of a severe brain injury. In intoxication the breath has the characteristic odor, the stomach content has alcohol in it and the blood stream is positive for alcohol. In a given case of intoxication without any head injury one finds a rapid pulse (almost thready), a florid flushed face, deep respirations with warm extremities. In a recovery from intoxication

one also finds tremulous hands, a positive Quinquaund sign, tremulous speech, tremulous tongue and a varied type of mental and emotional behavior ranging from violence and garrulousness to an ordinary sleepy state. "Punch drunk" is a term used to indicate organic brain disease in a fighter who has received many punches to the head as well as knockout blows on repeated occasions usually requiring weeks, months or years to develop.

COOKING PORK TO DESTROY TRICHINELLA

To the Editor:—I have read with great interest the article on trichinosis in the January 6 issue of The Journal. The article is thorough and satisfactory in every respect except in the matter of prevention. Mention is made of definite processing conditions for pork and pork products prescribed by the Bureau of Animal Industry of the United States Department of Agriculture. And then the statement is made that foods not so prepared should be thoroughly cooked. What is thorough cooking? For instance, how long should bacon be fried? How long should sausages be kept on the grill? How long should fried ham steak be on the fire? How long should pork chops be cooked? What temperature destroys Trichinella larvae? Would preliminary boiling in water destroy Trichinella larvae? If so, how long should the meat be boiled? It is really important to know these points because there has been considerable newspaper publicity about trichinosis and many people are asking these questions.

ANSWER.—Trichinella larvae are destroyed at a minimum temperature of 137 F., but it is apparent that every part of the cut being cooked must reach this minimum temperature. Perfectly safe procedure for the preparation of pork or products containing pork is to cook until well done. In the case of fresh pork, a good criterion is the disappearance of the pink color from the center of the piece of meat. In prepared pork such as bacon, the color is fixed so it will remain pink after cooking but the difference between rare and well done is so obvious that it can be recognized with assurance. Pork products cooked to the stage of well done will have reached a temperature of at least 170 F., which is a safety margin of 33 degrees F. over the 137 F. necessary to kill Trichinella larvae. It is impossible to answer this question in terms of the length of time that bacon should be fried, sausage kept on the grill, fried ham steaks on the fire or pork chops cooked, because the time of cooking is affected by the size of the cut, the nature of the container and the intensity of the flame used in cooking the meat.

Preliminary boiling in water to an inside temperature of 137 F. would destroy Trichinella larvae, but this particular method of applying adequate heat has no special virtue over other methods. Since it would affect the palatability of the product, it is not recommended. Pork cuts and pork preparations should be cooked by the methods which custom has established as producing the most palatable product and cooked for a sufficient length of time under conditions so that there is no trace of pink in the most central point.

SENSITIVITY TO TOBACCO SMOKE

To the Editor:—A patient complains of an almost continuous postnasal discharge and rhinitis. He has been examined by a competent nose and throat specialist, and a diagnosis of local sensitivity to tobacco has been made. The patient has complete relief from the rhinitis and pharyngeal drip almost immediately on stopping smoking. In addition he complains of occasional headache, chest pains, cough and dyspnea, all of which symptoms disappear on cessation of smoking. He has tried, on the advice of a physician, to smoke a "denicotinized" cigaret, and although he has tried several such brands he has had no relief. Is this a form of allergy to tobacco or some other constituent of the cigaret? Do you think the patient be properly desensitized? The patient is anxious to continue smoking, if he can be spared the aforementioned symptoms. Do you have any recommendations with regard to a specific remedy or mode of therapy to correct this sensitivity?

ANSWER.—Tobacco may cause symptoms of the upper respiratory passage in two ways: (1) as a nonspecific irritant with action similar to that of other fumes, e. g. gasoline, steam and smoke, and (2) as a specific allergen in an individual who is allergic. As it is the tobacco leaf itself to which sensitivity is exhibited rather than the active drug nicotine, obviously "denicotinized" cigarettes would be of no help as the tobacco leaf is still present. Sometimes another brand of cigarettes which may contain other volatile substances can be smoked without difficulty. Desensitization to tobacco by injections has not been found satisfactory. Avoidance of smoking is much better and is so recommended. Only about 1 per cent of patients suffering from asthma and perennial vasomotor rhinitis exhibit positive cutaneous tests to tobacco and clinically allergy to tobacco is rare. A large number of these patients, however, are irritated by tobacco smoke. Handlers of tobacco in factories may acquire a contact dermatitis.

Book Notices

Epidemiology in Country Practice. By William Norman Pickles, M.D., Medical Officer of Health, Aysgarth Rural District, Yorkshire. With preface by Major Greenwood, F.R.S., D.Sc., F.R.C.P., Professor of Epidemiology and Vital Statistics in the University of London. Cloth. Price, \$2.50. Pp. 110, with illustrations. Baltimore: William Wood & Company, 1939.

This well written book should be read by the practicing physician residing in rural or urban areas. The obvious desire to find the clinical and epidemiologic answer to the illnesses coming under the scrutiny of the careful and thoughtful physician should prove an inspiration to the reader. This striking paragraph of the introduction deserves full quotation:

The general practitioner is in the forefront of the battle and his experience must necessarily be personal and vital. No consulting physician can ever have the opportunity to follow the whole course of such a disease as epidemic myalgia in the same way as the general practitioner, because of the latter's more intimate association with his patients.

Modern public procedure certainly endorse these sentiments.

The second quotation, taken from page 5, middle paragraph, is all inclusive and exceedingly valuable advice:

The object of this book is primarily an attempt to stimulate other country doctors to keep records of epidemic disease and to put before them the unique advantages that their position gives them, to impress on those interested in epidemiology the value of the natural history method of investigation of these diseases, and to awaken some interest in the layman, whose help in these matters cannot be overestimated.

Of particular interest to health officers are the author's observations on the school teacher as an epidemiologist (p. 6), the reference to the school epidemic investigation of the Medical Research Council (p. 8), the sound advice to the young physician entering country practice to regard as a hobby if not otherwise the natural history of epidemic diseases (p. 9) and the comments of the often vexed question of school closure (p. 22). The chapter on epidemic catarrhal jaundice is alone worth the price of the book. Altogether this book is a welcome addition to the volumes in the field of medicine and public health, and it offers an example to the practicing physician in the manner cases of communicable diseases should be studied for informative data and reported to health departments for adoption of accepted or known methods of control.

The Electrocardiogram and X-Ray Configuration of the Heart. By Arthur M. Master, B.S., M.D., F.A.C.P., Associate in Medicine and Chief, Cardiographic Laboratory, The Mount Sinai Hospital, New York. Cloth. Price, \$6.50. Pp. 222, with 100 illustrations. Philadelphia: Lea & Febiger, 1939.

This monograph sets out to demonstrate that the electrocardiographic appearance is determined to a large extent by the contour, size and position of the heart in the chest. The author clearly demonstrates that considerable variations in the electrocardiogram can be caused in these ways and that the effect of these other factors must be excluded before the interpretation is made that an underlying myocardial disease exists. The monograph will be illuminating to those few cardiologists who tend to read into the electrocardiogram evidences of myocardial disease when they are not present. The subject matter has recently received new impetus and is becoming more and more widely recognized and, as the author states, the type of body structure, the position of the patient and the location of the heart in the chest must all be considered in arriving at an interpretation of a particular record. The development of each topic is begun with a historical survey and is followed by case presentations, each with illustrations of the electrocardiograms and teleoroentgenograms; the reproduction of these is excellent and the details of the x-ray plates are clearly discernible. The presentation, however, is disconnected; the facts are not sufficiently summarized, as could have been done by expanding the text and

adding short summaries to each section. The descriptions of the electrocardiograms are not consistent, and a number of obvious errors are apparent. For example, in figure 25 the author speaks of a large Q wave in lead 3, which is not apparent in the record. Similar errors in the text give the impression of superficiality on the part of the author which is regrettable. The subject matter includes a consideration of the effects on the electrocardiogram of age, of change in body position, of respiration, of body habitus, of hypertension, of valvular disease, of congenital heart disease, of pulmonary disease, of chest deformities, of pericarditis and of hyperthyroidism. This monograph is not suitable for the beginner in electrocardiography and is obvious to one of large experience. It is useful for the electrocardiographer of experience who has developed the habit of reading into the record more abnormalities than actually exist in the electrocardiogram.

In memoria del Prof. Fabio Rivalta: La "reazione di Rivalta," scritta mediet in suo onore. Società medico-chirurgica di Romagna. Paper. Price, 50 lire. Pp. 398, with illustrations. Faenza: Fratelli Lega, 1939.

The memorial volume published by the Medico-Chirurgical Society of Romagna in honor of Prof. Fabio Rivalta contains some excellent monographs by leading physicians and surgeons of Romagna and other parts of Italy who have either been associated with Rivalta personally or who are now at the head of medical clinics in hospitals where Rivalta served as physician-in-chief. The subjects range from lipoid nephrosis to undulant fever and to monographs on the last disease and death of the composer Bellini. There is also an excellent monograph on the use of insulin, modified by bicarbonate treatment.

The first reaction, introduced nearly forty-three years ago, affords a simple and reliable method of differentiating between transudates and exudates. This reaction is well known and described in almost all the textbooks on clinical and laboratory methods. Wells's "Chemical Pathology" and Kolmer's "Approved Laboratory Technique" give detailed description of the method. The second reaction, which Rivalta announced in the *Policlinico* in 1910, is almost unknown to the English speaking world. The first reaction can be easily performed by any laboratory technician. About 200 cc. of distilled water is placed in a conical beaker, and three drops of glacial acetic acid are added. After thorough mixing one or two drops of the fluid under examination are placed in this weak acid solution. A distinct cloud will be observed in the fluid if the material is an exudate, whereas the reaction will be negative if the fluid is a transudate. Professor Rivalta proved that this phenomenon is due to the presence in an exudate of large amounts of globulin, which is absent in transudates.

The second reaction has been introduced to give physicians a simple method of determining in serum and blood an index of antibody production, in both acute and chronic infectious processes. It is performed by placing in a conical beaker 200 cc. of distilled water and placing therein three drops of glacial acetic acid. In other containers the technician makes serial dilutions of blood serum and of whole blood from 1:200 to 1:2,000 in a weak alkaline solution of distilled water (distilled water 100 cc., sodium carbonate saturated solution one drop). By performing the reaction with varying dilutions of the patient's serum ranging from 1:200 to 1:2,000 one can get an approximate quantitative idea of the antibody production taking place.

The hemoreaction and the scroreaction of Rivalta seem to have been studied on a large number of patients in many chronic and acute infectious processes. From the monographs contained in this volume by Chiadini it seems that these reactions are growing in popularity. Both reactions are simple and any laboratory technician can perform the test in a few minutes. It is noteworthy that a close parallelism has been found between the quantitative reactions and the leukocytosis. Gironi presents also an important monograph showing that the reaction appears to be indicative of the amounts of antitoxin present in the serum. He has immunized animals with ricin and found that with the production of antiricin the reaction becomes positive in higher and higher dilutions as the titer of antiricin increases. As the antibody titer begins to go down the reaction also continues positive only in the lower dilutions. It is to be hoped that clinical pathologists and biochemists will be attracted to these

simple methods of obtaining a glimpse of the immunity reaction going on in the animal and in the patient. This method may supply to the clinician a prognostic sign of the highest value and from the monographs reviewed it appears that many great clinicians in Italy have actually found the seroreaction of unquestionable merit in prognosis.

To the chemist and biochemist, working in laboratories, devoted to the production of antitoxins and antisera, this reaction supplies a reliable and inexpensive method of determining the potency and also knowing when the animal under immunization has reached the highest level of antibody production and then proceed from this point to subject the serum to the quantitative methods of potency assay expressed in units per cubic centimeter. This would eliminate the necessity of costly and time consuming assays during the process of immunization and would afford a simple inexpensive means of knowing, at intervals, in the process of immunization, how well the antitoxin production was going on in the animal.

Blood Groups and Blood Transfusion. By Alexander S. Wiener, A.B., M.D., Serologist and Bacteriologist in the Office of the Chief Medical Examiner of New York City. Second edition. Cloth. Price, \$5. Pp. 306, with 52 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

This edition has been revised to include the advances in the knowledge and practice of blood grouping since the issue of the book in 1935. Transfusion and the medicolegal uses of blood group tests have received special consideration. The main topics of the contents are the four blood groups and their use in the selection of donors in transfusion, in anthropologic studies, in cases of disputed parentage and in the identification of stains. There are chapters also on the heredity and constitutional nature of blood groups; on agglutinogens M and N, their heredity; on subgroups A and AB; on individual differences in animal blood, and on blood groups in relation to disease. Blood transfusion is discussed with respect to history, selection of donors, technique, indications and results. The book is a standard work in its field, which it covers competently and comprehensively. It will be of interest and value not only to those concerned with blood transfusion and with problems of parentage and identification but also to the immunologist, the geneticist and the anthropologist.

Die Gonorrhöe der Frau: Ein Leitfaden für die Praxis. Von Dr. Karlheinz Sommer, Marlinestabsarzt z. Zt. Komm. an die Universitäts-Frauenklinik Leipzig. Paper. Price, 8.50 marks. Pp. 185, with 47 illustrations. Leipzig: Georg Thieme, 1939.

This monograph is well done and is nicely illustrated with both gross and microscopic plates. The subject is approached with an underlying study of the anatomy and physiology of the female generative tract. The subject of gonorrhea is taken up from the bacteriologic point of view before the discussion of the effects of the disease on the female. The disease in women is studied from the result on the lower and then on the upper tracts. Treatment is adequately covered, with mention being given to all used forms of treatment. Gonorrhea in pregnancy and the remote complications of the disease are also covered. For one who is especially interested in the subject this little book should be of great value.

Études neurologiques. Huitième série. Par Georges Guillaumin, professeur de clinique des maladies du système nerveux à la Faculté de médecine de Paris. Table générale des matières des "Études neurologiques" (séries I à VIII). Paper. Price, 90 francs. Pp. 419, with 72 illustrations. Paris: Masson & Cie, 1939.

Guillaumin, the author of the present collection of reprints, is a successor of Charcot, Dejerine and Marie as professor of neurology in the Faculty of Medicine in the University of Paris and neurologic director of the Salpêtrière. The present volume is the eighth of a series, all planned on the same principle, each containing a collection of reprints by Guillaumin which have been published elsewhere with a few exceptions. This book concludes with an index to all the eight volumes which have appeared. The present volume is made in five parts. The first part contains five articles dealing with the pathology of the brain. The second part contains five articles on the peduncles, mouth and cerebellum. The third part contains only three articles on the spinal cord. The fourth deals with pathology of the cranial and spinal nerves, and in it five subjects are discussed. The last section is the largest, having ten varied reprints dealing with

such subjects as the clinical and biologic study of the care of acromegaly, a discussion of a case of milkman's syndrome and a study of the labyrinth in Paget's disease. All these papers are excellent and represent the best of French neurology. They are composed either of one thorough case history with the pathologic changes observed or they present topics which are illustrated by a number of case histories. One of the papers is in English and carries with it a French translation. This paper is on radiculoneuritis with acellular hyperalbuminosis of the cerebrospinal fluid, which appeared in the *Archives of Neurology and Psychiatry* in November 1936. For those physicians who read French and who wish to be acquainted with a good sample of French neurology, this collection of reprints would be of great value. In fact, one can urge on the neurologist a thorough acquaintance with all the eight volumes of reprints in this series by Guillaumin.

Lehrbuch der allgemeinen Pathologie und der pathologischen Anatomie. Von H. Ribbert. Bearbeitet von Professor Dr. H. Hamperl, Prosektor am Pathologischen Institut der Universität Berlin (Charité-Krankenhaus). Twelfth edition. Paper. Price, 27 marks. Pp. 634, with 700 illustrations. Berlin: F. C. W. Vogel, 1939.

For this hurried and harried generation of medical students the name of Ribbert can have little significance; indeed, a possible suggestion of antiquity implied in a twelfth edition would presumably deter rather than recommend perusal. But survival does at times indicate usefulness, and this new Ribbert, revised by Hamperl, is definitely a useful book. One might designate it a streamlined edition, if such a descriptive term is permissible in connection with so orthodox and orderly a subject as general pathology has become in the decades that have followed the exciting era of Virchow. The editions of Ribbert which were edited by Mönckeberg and later by Sternberg more than maintained the earlier traditions. The present text, while adhering to the original, has greatly amplified and broadened the point of view, so that it is quite abreast of modern trends and much has been added in illustrative material, which is in the main excellent in character and selection. Hamperl is primarily the morbid anatomist trained in the Viennese school; it is natural that it is form, rather than form plus function, that colors the book, but it would probably be asking too much in a textbook of pathology to reflect changes in clinical thought that are far in advance of the postmortem room and the histopathologic laboratory. Virchow himself was primarily the physiologist who taught pathologic anatomy, but with the course of time and the crystallization of departmental teaching the morbid anatomist can hardly be expected to teach pathology and to write textbooks that would treat of function rather than form. Of all modern textbooks one finds a consistent effort to do just that only in Tendeloo, and this book has never been popular in either continental or American schools. All of which by no means detracts from the recognition of the excellent quality of the new edition, which presents general as well as special pathology in a well illustrated, well balanced and orderly fashion. Attributes such as these have made the Ribbert an exemplary student textbook for several generations. But this, as a natural corollary, must exclude features which might make the book more useful for the clinician and the investigator. An interesting innovation is found in footnotes that give both Greek and Latin derivation of descriptive terms—in itself an interesting sidelight into the modern German educational system. In Ribbert's day a thorough grounding in the classics was still obligatory.

Gynecology: Medical and Surgical. By P. Brooke Bland, M.D., F.A.C.S., Consulting Obstetrician to the Jefferson Medical College Hospital, Philadelphia. Assisted by Arthur First, M.D., Associate in Obstetrics, the Jefferson Medical College Hospital, Philadelphia. Third edition. Cloth. Price, \$9. Pp. 843, with 445 illustrations. Philadelphia: F. A. Davis Company, 1939.

According to the preface, the author has practiced gynecology for more than thirty-five years. His book describes the sound principles and conservative methods resulting from this long experience. It is a good textbook, well proportioned, full and accurate, but it has two obvious weaknesses. The first is prolixity. At present a crisp factual style is preferred; the third edition has been rewritten but it is filled with the slow phraseology of the first (1924). The second weakness is the paucity of fact. Advantage has not been taken of the abundant literature

of gynecologic statistics. For example, gynecologists agree that approximately 25 per cent of patients with carcinoma of the cervix in a well treated series will survive five years or more after treatment. On this subject the author says "The duration of life . . . is longer in body than in cervical carcinoma." Nowadays such vagueness is unsatisfying. Facts are available; let us have them! The reader will find the literature nicely tabulated in a separate chapter of twenty-seven pages on referred reading. Illustrations are good and the color plates of normal and pathologic organs are superb. This volume will be more useful to undergraduates than to practitioners.

Psycho-Dynamics of Chewing. By H. L. Hollingworth. *Archives of Psychology*, No. 239. Paper. Price, \$1.50. Pp. 90. New York: Columbia University, 1939.

By what appear to be adequate experiments on twenty human subjects, the author endeavors to explain the role of sustained mastication in the psychophysical economy of human activity. This mastication is not that of chewing a meal but chewing on gum or on indifferent substances when at rest or when busy with other mental or physical work. The several lines of experiments indicate clearly that such chewing results in a decrease of neuromuscular tension and most of the subjects reported that they actually felt more relaxed as a result of the chewing. The slight physical cost of the chewing process itself may thus result in economy by muscular relaxation in the rest of the body. The author suggests that this relation between sustained chewing and relaxation is a carry over from the fact that, in civilized man at least, the mastication in connection with eating is usually accompanied by sitting down and otherwise relaxing. This is an interesting and possibly significant study. One stenographer showed increased speed in typing while chewing. Another showed increased speed but decreased accuracy. In the main this work indicates that there may be more physiologic significance to the gum chewing habit of Americans than would appear on the surface.

A Survey of Hospital Services and Finances in the Philadelphia Area Based on Data Collected from 67 Philadelphia Hospitals for the Year 1937. Sponsored by the Hospital Council of Philadelphia. Paper. Price, \$1. Pp. 59. Philadelphia, 1939.

This report on the survey of hospital services and finances in the Philadelphia area is best summed up in its own statement of conclusions and recommendations, in which it is stated that the purpose is to describe the amounts and types of services rendered and that it was not intended to establish categorical conclusions or to set up a qualitative scale for measuring hospital service. It is stated, nevertheless, that the task of gathering the data would hardly be justified without some suggestions, and with this in mind the author makes fifteen suggestions looking toward the improvement of hospital service in the Philadelphia area. These conclusions and recommendations might apply to other areas as well. In fact, the whole report furnishes profitable reading for those interested in hospital service for any given community.

Obstetrícia normal. Pelo Professor Raul Briquet, lente catedrático de Clínica obstétrica e puericultura neo-natal da Universidade de S. Paulo. Cloth. Pp. 538, with 427 illustrations. Rio de Janeiro: Livraria Editora Freitas Bastos, 1939.

This volume on normal obstetrics represents an outline of present day obstetric thought and teaching. Its content is limited to the problems of normal midwifery, so that this book should meet a real need in South American countries, for which it was probably written. The general practitioner will find a wholesome presentation. The book opens with a chapter on the medical historical background of pregnancy and labor and ends with a chapter dealing with the newborn. The physiology and conduct of pregnancy and labor are described and profusely illustrated. There is a long chapter on multiple births and the problems which these entail. The book could be improved by a more detailed description of some of the major complications of pregnancy, such as infection, toxemia and hemorrhage, for these cannot be divorced from normal obstetrics. Many illustrations have been taken from Bumm's textbook and De Lee's Principles and Practice of Obstetrics. The quality of the illustrations, the paper and the binding could be greatly improved on.

Physiology in Health and Disease. By Carl J. Wiggers, M.D., Professor of Physiology in the School of Medicine of Western Reserve University, Cleveland, Ohio. Third edition. Cloth. Price, \$9.50. Pp. 1,144, with 218 illustrations. Philadelphia: Lea & Febiger, 1939.

The present edition is a great improvement over the first. A number of new illustrations have been added. The entire section on muscle has been rewritten and rearranged, as has also the second section on neurophysiology, so that both read much more smoothly. Despite the inclusion of new material, the total number of pages is slightly less than in the first edition but considerably greater than in the second edition. Despite the general improvement in composition, the subject matter appears to be still rather unbalanced. The number of pages in the section on neurophysiology has been increased, but in most of the other sections except the one on circulation the number has been reduced. This may perhaps be justifiable in most instances but certainly gastrointestinal physiology and metabolism deserve more balanced treatment in comparison to circulation. The illustrations are excellent. The author has maintained the policy of putting references in footnotes on the pages where used. This facilitates to some extent the checking of references by readers. Instances of unusual and even incorrect word usage are rather more frequent than one expects in a scientific work of this caliber, e. g. "exorbitant" for "excessive" (p. 980). However, the subject matter is sound.

The British Encyclopaedia of Medical Practice including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. Volume XII: Tetanus to Yellow Fever. Cloth. Price, \$12. Pp. 672, with 48 illustrations. Toronto & London: Butterworth & Co., Ltd., 1939.

The latest volume of this notable series carries all of the conditions from "tetanus" through "yellow fever." This means, of course, such important subjects as the thymus, tonsils, toxicology, trachoma, tuberculosis, tumors, urine, uterus, vertigo, vitamins and whooping cough. Such distinguished names as those of Kenneth Walker, Manson Bahr, McCallan and Sir Leonard Rogers are an indication of the high quality of material that this volume provides. It is quite up to the previous volumes in this excellent series.

Therapeutisches Taschenbuch der wichtigsten Krankheiten der warmen Länder: Ein kurzer Ratgeber. Von Prof. Dr. P. Mühlens, Direktor des Instituts für Schiffs- und Tropenkrankheiten, Hamburg. Boards. Price, 2 marks. Pp. 73, with 16 illustrations. Leipzig: Georg Thieme, 1939.

This pocket handbook discusses the main clinical features, prevention and treatment of the principal tropical diseases. Discussions are so brief and sketchy that one can scarcely credit its intended use for the medical profession. It is an example of oversimplification.

Clinical Diagnosis by Laboratory Methods: A Working Manual of Clinical Pathology. By James Campbell Todd, Ph.D., M.D., and Arthur Hawley Sanford, A.M., M.D., Professor of Clinical Pathology, University of Minnesota (The Mayo Foundation), Rochester. Ninth edition. Cloth. Price, \$6. Pp. 841, with 368 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

The revision of this book brings it abreast of the time, as far as this can be done with a standard textbook. Most notable additions are the new section on hematopoiesis and the methods for the Bodansky determination of phosphate and phosphatase, the Power and Wakefield sulfate method, the hippuric acid test and serum lipase, ascorbic acid and sulfanilamide determinations. As it has always been, this book is a fine textbook for laboratory technicians and should be included in every laboratory no matter how small that laboratory may be.

Die Gonorrhöe in der Allgemeinpraxis. Von Professor Dr. Paul Mülzer, Direktor der Universitäts-Klinik für Haut- und Geschlechtskrankheiten in Hamburg. Paper. Price, 8.40 marks. Pp. 125, with 10 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

This small volume covers gonorrhea in both the male and the female. The subject is taken up from the bacteriologic and clinical points of view and is well handled. Although meager in illustrations, the text is fairly complete. Particularly interesting is the section on treatment, in which heat and specific chemotherapy with sulfanilamide are discussed. In the section on infantile vulvovaginitis, mention is not made of estrogenic therapy.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance: Death Following Administration of Neoarsphenamine.—The defendant insurance company promised to pay to the beneficiary certain benefits if the death of the insured resulted from bodily injury effected solely through external, violent and accidental cause and not from physical or mental infirmity or illness or disease of any kind. The insured had syphilis and was receiving medical treatment consisting of alternate hypodermic injections of bismuth and neoarsphenamine. Following the fifth administration of the arsenical, administered about a month after the first, the insured suffered a violent reaction and died. The insurer refused to pay the beneficiary, the beneficiary sued, the trial court directed a verdict for the insurer and the beneficiary appealed to the supreme court of New York, appellate division, first department.

The quantity of neoarsphenamine injected had commenced with 0.3 Gm. and was gradually increased to 0.6 Gm. and had been administered in the customary manner and without untoward incident. The physicians called as witnesses for the beneficiary testified that unfavorable reactions to injections of neoarsphenamine occur very rarely, that the average risk of death is about one in 7,000 to 11,000 instances but that an unfavorable reaction to the drug is always a possibility. They stated that medical science has no way of anticipating which patient will be hypersensitive to the drug. These witnesses testified, too, that the existence of a syphilitic condition in the insured in no way contributed to his death, although it was because of the presence of that disease that the drug was administered. In their opinion the death resulted directly and solely because of the treatment being received by the insured.

To the court, it was clear that the death resulted from an accident within the meaning of the insurance policy. It has been held, the court pointed out, that if a fatal infection results from the use of a hypodermic needle the case is one of accidental death within the meaning of a similar insurance policy. The fact that the insured intentionally incurred the administration of the drug did not preclude a finding that death occurred through accidental means. In the present case, the hypodermic needle did not introduce a germ or other foreign substance which caused infection; it merely introduced the drug sought to be injected. Death, however, occurred from the extremely rare circumstance that the insured had some physical peculiarity that made him hypersensitive to the neoarsphenamine. The predisposition to unfavorable results from neoarsphenamine did not constitute an infirmity or disease within the meaning of the policy.

The judgment of the trial court was reversed and a new trial ordered.—*Berkowitz v. New York Life Ins. Co. (N. Y.), 10 N. Y. S. (2d) 106.*

Optometry: Obtaining Money Under False Pretenses.—For a period of four years the accused drove a car for an optometrist and acted as a "flunky" for him, carrying his instrument case and generally helping him in his work. During these years the optometrist traveled extensively through southern Missouri. After the traveling optometrist quit that territory, the accused formed an association with one King, and the two went about examining eyes and prescribing glasses. During the course of their "practice" they examined the eyes of the Cooper family, consisting of the husband, the wife and a child. This family was induced to buy three pairs of spectacles for which the husband gave to the accused checks in the amount of \$59.94. The spectacles were to be delivered within a few days but were in fact never delivered. The checks were cashed by the accused and thereafter he was convicted on a charge of obtaining money under false pretenses and appealed to the Supreme Court of Missouri.

Neither King nor the accused had licenses to practice medicine or optometry. The state introduced substantial evidence tending to prove that the accused stated to a number of persons that he was a physician and had been practicing medicine in

Springfield; that "Dr. King" had treated eyes and fitted glasses for many of his, the accused's patients, and had always given satisfaction; that he, the accused, and King had rented rooms at West Plains and were going to locate there and that if the glasses they sold were not satisfactory they would make adjustments. One witness and his wife testifying for the state said that they had bought spectacles from the accused and King and had paid them. The receipt given for this payment was signed by the accused as "Dr. B. H. Craft, 456 Market Street, Springfield, Missouri." Mrs. Cooper testified that when King was "pretentiously" examining her eyes he looked up at the accused and said "Doctor, haven't I treated lots of your patients and always given satisfaction in fitting glasses?" and that the accused replied "You sure have." The accused contended that he acted merely as a "flunky" for King, as he had done for the optometrist, and that King pretended to be an eye specialist but that he later found that "the highest ranking King ever obtained was that of a prizefighter." The court, however, was apparently not impressed with the contentions of the accused and after examining the entire record found it free from error. The judgment of conviction was therefore affirmed.—*State v. Craft (Mo.), 126 S. W. (2d) 177.*

- Tennessee State Medical Association, Chattanooga, Apr. 9-11. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Psychiatry, New York

96: 517-770 (Nov.) 1939. Partial Index

- Significance of Special Mental Tests for Diagnosis and Prognosis in Schizophrenia. K. Goldstein, New York.—p. 575.

- Psychiatric Aspects of Porrocephaly. E. L. Bernstein, Arlington Heights, Mass.—p. 723.

Metrazol for Acute Alcoholism.—Orenstein and his collaborators treated two types of acute alcoholism with metrazol. One type consisted of a group of thirty-four patients who had a history and evidence of recent alcoholism and a clinical picture of acute disturbance, resistance and violence; the other group of sixteen patients had the same history as the first and deep coma or coma complicated by respiratory failure. Immediately after admission such patients were taken to the emergency room and were given intravenously 5 cc. of a 10 per cent solution of metrazol, the rate of injection being about thirty seconds for the 5 cc. This speed of injection failed to induce a general convulsion in the patients narcotized with alcohol. In some individuals, twitching of the face appeared. The authors refer to this dose and time factor as a "subconvulsive dose," that is the dose is large enough to stimulate the central nervous system notably but does not lead to a generalized seizure. Sedation and other treatment were ordered as indicated. A large number of the excited patients would quiet down in from two to ten minutes after the injection and no further special treatment would be necessary. Comatose patients frequently regained consciousness in from five to thirty minutes and were able to give an adequate admission history. Twenty-five of the thirty-four excited patients improved within twenty minutes after the injection of metrazol, that is the acute symptoms of excitement disappeared. Ten of the sixteen comatose patients improved within thirty minutes, that is they awakened within this time or there was a change in their respiratory function with a clearing of the cyanosis or other alarming signs.

Psychoses Associated with Epilepsy.—Clark and Lesko state that in one year twenty-two patients were admitted to the Boston Psychopathic Hospital because of psychoses associated with epileptic seizures not complicated by syphilis, brain tumor, recent head injury or other causes of extensive damage to the central nervous system. Fourteen of the patients had clouded states, three chronic psychoses, one deterioration with psychoses and one a severe behavior disorder, and three could not be classified. Their ages, on first becoming mentally ill, ranged from 12 to 49 years. In all a considerable interval (from two to forty-five years, average about fifteen years) elapsed between the onset of their seizures and their first attack of mental

illness. Their family histories with one exception (a family history of epilepsy) were not remarkable. Only four other patients were known to have a parent with signs of nervous abnormality: two alcoholic, one depressed and one migrainous. Eleven patients had early cerebral damage although there were no residual neurologic signs. All patients had typical grand mal attacks without localizing features; five also had petit mal attacks. The frequency of seizures varied greatly, one patient having only nine observed seizures in the previous six years, another having grand mal attacks up to seven times daily. The average was about once a month. Patients with clouded states had the condition from about half a day to thirty-five days, with an average of four and a half days for twenty-one episodes. Usually these states were preceded by one or more grand mal seizures. All the patients with clouded states were overactive at some time (from mere restlessness to extreme combativeness and assaultiveness). Only two were stuporous for short periods. Speech and mood were variable. Delusions were manifested by twelve patients. Twelve had hallucinations, eleven of whom had delusions as well. Six had visions, including dead people, snakes, pigs, bugs, pigmy men and various living people. Seven had auditory hallucinations, including voices, music and the sound of airplanes. There were no olfactory, tactile or gustatory hallucinations. Of those who responded to questions, only two had unimpaired memories. The memories of others were better preserved for remote than for recent events. When orientation could be determined, it was poor in all but one case. Insight during attacks was absent in those with great overactivity and disturbed moods, while in calmer patients insight was partially present. The degree of amnesia for the attack after recovery was greatest when the most excitement prevailed during the psychosis and was least in the more elaborate, dream-like states. The clouded states were comparable to alcoholic intoxication. The neuropathologic processes underlying these conditions are unknown. There is great need of research in this field.

Deaths from Farm Accidents in Alabama.—Baker presents data secured through accident questionnaires collected over seven years (1932-1938) by the Bureau of Vital Statistics. Every certificate of death filed in the Bureau of Vital Statistics of the Alabama State Board of Health on which the medical certification gave an accidental cause of death was queried. Of 309 deaths from farm industrial accidents recorded 186 deaths were of white persons and 123 of Negroes. Only eighteen were women. Of the deaths 46 per cent occurred during the four summer months. About one third of the deaths occurred instantly; one half within twenty-four hours and 78 per cent within one week. The interval between the time of the accident and death ranged from instant death to a maximum of 932 days. Of all known farming activities, cutting and sawing lumber was recorded once for every five farm industrial deaths. In three out of four deaths from this activity a falling object was the destroying agent; 79 per cent of these objects were falling trees.

Caring for animals was the cause of thirty-seven deaths. Fourteen of these deaths involved mules and in ten instances the animal kicked its victim to death. Plowing was the third activity in importance, resulting in thirty-one deaths, ten of which were from being struck by lightning. Eight were attributed to sunstroke. Driving vehicles caused the death of twenty-two persons, three fourths of whom fell—fourteen from wagons and two from trucks. Clearing of land was the fifth activity of importance, resulting in seventeen deaths, more than three fourths of which were caused by burns. Of equal importance to the activity of clearing land was that of riding animals, which also resulted in seventeen deaths. Eleven of the deaths were caused by the rider becoming entangled in the harness and being dragged by mules. About one half of the deaths from riding animals were of young people (10 to 14 years of age). Almost all of the decedents in this category were less than 25 years of age. From 1933 to 1938 inclusive there were 1,594 lives sacrificed by accidents in farm homes (deaths of persons residing on farms but not gainfully employed at the time). Of these 960 were white persons and 634 were Negroes; 512 and 325 respectively were women. Only one fourth of the fatal home accidents occurred during the four summer months; 40 per cent of the home accidents occurred during four winter months (October-January). Just as in the case of farm industrial accidents, a large number of the decedents die shortly after the accident occurs. Playing comprised one out of five of all activities ending in death, and burns constituted the destructive agency in more than half of the deaths (115) which occurred while playing. Almost all of the victims were less than 5 years of age. Falls were the second most important agency of injury in the playing group. Of twenty-one gunshot deaths, fifteen were the result of some one playing other than the decedent. There were 185 deaths from accidents which occurred while walking. Falls accounted for 51.1 per cent of these deaths. Sleeping, the third most important (13.5 per cent) activity, was associated with 159 accidental deaths, 56 per cent of which were from suffocation. The agency of injury second in importance in this group was burns (burning buildings). Standing was associated with the death of 134 individuals. Standing before an open fire was the origin of fifty-nine of these deaths. Falls, the second agency of injury in importance, accounted for twenty-six deaths. Eating and drinking, the activity fifth in importance, terminated fatally for 120 persons, of which number ninety-five were attributed to poisoning. Food poisonings totaled forty-five. Of the fifty remaining deaths, twenty-three were from lye poisoning. Rat poison was charged with four deaths, kerosene with three. Twenty-four of the eating deaths were from suffocation, fourteen of which were caused by foreign bodies. Falls from the sitting position caused nineteen deaths. The taking of medicine resulted in twelve deaths. A "patent medicine" for the treatment of worms caused one death. In two instances oil of chenopodium was concerned. Forty-four fatalities were in homes in which the decedent lived alone or was alone at the time of the accident; sixteen were infants of 1 year or less; five infants crawled into open fires. Information on the prevention of farm accidents should be made available to all schools and to the farm group.

Menstrual Cycle and Serologic Test for Syphilis.—The occasional clinical observation that an apparently false positive blood serologic test for syphilis can be obtained at about the time of menstruation has led Ingraham and Mayer to perform 292 separate tests on sixty-six specimens of blood obtained from seventeen healthy young women. The blood samples were studied on various days of the menstrual cycle. The results

were uniformly negative throughout. The conclusion is that false positive serologic tests occurring during the menstrual cycle must result from a peculiarity of the individual or of the test and do not arise from any uniform blood changes occurring in all women. The incidence of occasional exceptional cases can be deduced only by studies of large groups of women.

Vitamin C and Surgery.—Bartlett and his associates determined the vitamin C content of the blood plasma of thirteen normal subjects and of 188 patients to be operated on. The thirteen control subjects showed a blood plasma content varying from 0.77 to 1.62 mg. per hundred cubic centimeters, with an average of 1.24 mg. Of the 188 patients on whom fasting determinations were made the average blood plasma level was 0.43 mg. per hundred cubic centimeters, with a variation from zero to 1.89 mg. As a concentration below 0.5 mg. per hundred cubic centimeters was obtained in 126 of the patients, this may be considered definitely abnormal with respect to their vitamin C metabolism. To determine whether the type of disease has a bearing on the degree of depletion the patients were divided into several groups, and also the vitamin C content, with its possible effect on the healing process, was determined postoperatively. The authors feel that the consistent fall in the plasma vitamin C observed after operation cannot be accounted for entirely on the basis of decrease in vitamin C intake. Most of the patients studied were allowed fluids by mouth, including fresh fruit juice, immediately after operation, so that an adequate supply of vitamin C was available throughout the postoperative interval. The drop in the plasma vitamin C in several instances was far too abrupt to be accounted for on the basis of starvation alone, even if the diet after operation contained no vitamin C. The changes in contour observed in the clearance curves after operation do not seem to be dependent on a decrease in vitamin C intake, the amount of parenteral fluid administered or the type of anesthesia. There is some evidence which suggests that the magnitude of the surgical procedure is related to the extent and duration of the postoperative alteration in the curves. The general preoperative nutritional state and especially the degree of vitamin C depletion seems to be another important factor. If the preoperative nutrition is good and the vitamin C is not depleted the more extensive surgical procedures cause a less marked change in the postoperative vitamin C clearance curves. A fall in the fasting plasma level of ascorbic acid occurs immediately after operation with a gradual return to the preoperative level, and when an intravenous dose of 1,000 mg. of ascorbic acid is given it is removed from the blood stream more rapidly than before operation, possibly because of an increased need for this substance during the process of tissue repair and wound healing. Depletion of vitamin C is found in patients with a variety of pathologic conditions.

Sulfanilamide for Appendical Peritonitis.—In 1936 Raydin and his colleagues began to use sulfanilamide in spreading peritonitis associated with acute appendical infections and

also when it was feared that a spreading infection might develop. A compilation of the mortality figures in 809 consecutive cases of acute appendicitis shows that the mortality has been reduced from 1.5 per cent of the 552 patients operated on previous to the use of sulfanilamide to 0.4 per cent of the following 257. The improvement, they believe, can be attributed only to the employment of sulfanilamide, as no other known factor was changed. A number of patients with extensive peritoneal infection secondary to appendicitis recovered with much less reaction than would have been predicted on the basis of experience with the first 552 cases. All the available evidence indicates that the peritoneum is a favorable site for the action of sulfanilamide. It appears that the character of the lesion is more important than the specificity of the organism in determining the effectiveness of the drug. No instance of intestinal obstruction due to adhesions has been encountered since suction drainage of the stomach has been employed.

New Incision for Infections Involving Fingertips.—Weiner describes a new incision for closed space infections which appears to eliminate the objectionable features of other incisions. Under gas-oxygen anesthesia the nail is detached from the skin, nail bed and matrix. An inverted U shaped incision is made close to the tuft of the bone and part of the shaft of the distal phalanx. The perpendicular fibers are cut close to the bone. The pulp is retracted and the closed space is entered. The abscess (felon) is found lying just anterior to the distal phalanx. The mushroom portion of bone is carefully examined for evidences of osteomyelitis and if signs of softening are present the tuft is removed. The abscess cavity is emptied and the necrotic tissue in the anterior space, if present, is cut away and iodoform gauze is packed into the cavity. Wet dressings of boric acid are applied. The patient is instructed to soak the finger in hot boric acid solution every two hours for twenty minutes. The packing is removed in forty-eight hours. The author states that the advantages of the incision are that the bone is brought closer to the surface and less soft tissue has to be cut through, early osteomyelitis can be detected long before a roentgenogram reveals such destruction, adequate drainage is obtained, the wound heals in a shorter time, if a sequestrum forms it can be easily extruded, scarring is absent as the nail regenerates and covers the scar, and sensation is unimpaired.

Nicotinic Acid and Vitamin B₁ for Multiple Sclerosis.—Moore reports five cases of advanced multiple sclerosis in which nicotinic acid therapy was used, in the first case on Feb. 15, 1938, and has been used almost continuously, with a few interruptions, until the time of writing. Until June 1938 the

nicotinic acid was given intramuscularly (from 60 to 120 mg. in 10 cc. of sterile physiologic solution of sodium chloride) on alternate week days. After June 4, 1938, the drug was given intramuscularly exclusively, in doses varying from 80 to 140 mg., two or three times a week, depending on the patient's reaction. At this time the use of vitamin B₁ (thiamin chloride) was begun and 3.32 mg. (1,000 international units) was administered intravenously at the height of the cutaneous hyperemia. After July 18, 10 cc. of nicotinic acid and thiamin chloride combined in solution with sterile distilled water was injected intramuscularly into the buttocks, each cubic centimeter containing 12 mg. of nicotinic acid and 3.32 mg. of thiamin chloride. The solution was heated to about 110 F. and drawn into a warm syringe barrel immediately before injection; otherwise the characteristic flushing of the skin and body warmth did not occur. Prior to the use of nicotinic acid and vitamin B₁ the five patients received various treatments. Only hyperpyrexia appeared to produce a temporary improvement in most instances, except in case 5, in which the condition was made worse. The beneficial effects of vasodilatation and increased blood flow achieved by fever therapy and sympathectomy could be obtained with nicotinic acid without the dangers incident to these methods. Improvement followed the parenteral use of nicotinic acid and vitamin B₁ in the five cases of multiple sclerosis. Nicotinic acid produces vasodilatation and increased blood flow in the brain and spinal cord. The rise of cerebrospinal fluid pressure, as observed in cases 1 and 4, following the injection of nicotinic acid and, coming on coincidentally with the subjective feeling of warmth and the objective appearance of flushing of the skin, was presumptive evidence of vasodilatation within the brain. The exposed brain and cervicothoracic portion of the cord of the cat showed vasodilatation both visually and photographically after the intramuscular injection of nicotinic acid; this was most evident at the height of "pinking" of the cat's tongue and dental mucous membrane. When nicotinic acid-vitamin B₁ therapy was discontinued for any length of time, incapacitating spasticity and incoordination returned in every case. These symptoms were ameliorated within several days, or at most a fortnight, on restitution of treatment. To date untoward effects of prolonged treatment with nicotinic acid and vitamin B₁ have not been encountered, and laboratory and electrocardiographic studies have not shown evidence of harmful effects. Complete remissions have not been achieved. On the other hand, these cases were instances of advanced multiple sclerosis in which many forms of therapy had been used without appreciably arresting the progress of the disease. After treatment with nicotinic acid and thiamin chloride every patient noticed improvement in bodily movements and in walking: Patient 2 has been restored to her aptitude at the piano and has lost the annoying paresthesias. Patient 4 is now able to stand and has overcome much of his extreme spasticity. Patient 5 is no longer bedridden; he can move his legs and stand while assisted and use his arms, which were previously powerless, for purposes of dressing and eating. What effect nicotinic acid-vitamin B₁ therapy may have in cases of early multiple sclerosis is still to be determined.

Effect of Liver and Iron Therapy on Atrophic Gastritis.—Schindler and his associates employed substitution therapy (liver and iron) in eight cases of atrophic gastritis not associated with pernicious anemia, combined cord degeneration, sprue or pellagra. Only cases were chosen in which the gastroscopic appearance was marked and in which repeated gastroscopic examinations were possible. The developments in case 1, a case of untreated atrophic gastritis, are reported as control observations. Cases 2, 3 and 4 are instances of severe atrophic gastritis in which substitution therapy was unsuccessful. In cases 5, 6, 7 and 8 liver therapy led to the apparent regeneration of the gastric mucosa. In case 9 liver therapy was unsuccessful, while treatment with iron was followed by mucosal regeneration. In case 1, not treated by substitution therapy, gastroscopic check: eight months after the initial gastroscopic examination showed no essential change in the mucosa, although clinical improvement occurred with a bland diet and sedatives. In case 5 spectacular improvement of extensive atrophic gastritis followed the first course of liver therapy, although slight areas of atrophy still were visible. The original picture reappeared after liver therapy was discontinued. There was no improvement after a second

course of therapy. Further study is required to evaluate its effectiveness. The case is of interest because free hydrochloric acid appeared after liver therapy, perhaps suggesting a true regeneration of functionally active glandular structures in the stomach, even though the improvement was temporary. Case 6 is the first instance of marked atrophic gastritis in which an apparent improvement was observed following liver therapy. The significance of the therapeutic result was further emphasized by the reappearance of the typical gastroscopic signs of atrophic gastritis after the patient discontinued treatment. Spontaneous improvement of severe atrophic gastritis was observed in case 7. Three gastroscopic examinations before the institution of liver therapy showed no improvement in this case and serve as control observations. The sudden disappearance of the atrophy following a brief period of liver therapy suggests a specific therapeutic result. A definite improvement of the atrophic gastritis in case 8 followed liver therapy. The case demonstrates that free hydrochloric acid may be present despite extensive atrophy of the gastric mucosa. In case 9 apparent healing of the atrophic gastritis associated with hypochromic anemia followed iron therapy. Apparent healing of atrophic gastritis following iron therapy has been described by Chevallier and Moutier and by Schiff and Goodman. This is the first case in which the authors have made the same observation. It is impossible at present to say whether or not the apparent regeneration of the gastric mucosa is genuine, i. e. due to the formation of new glands. Microscopic studies are necessary to solve this question. Substitution therapy, such as the administration of liver, iron or vitamins, is justified in the treatment of atrophic gastritis as an approach to clarifying the nature and pathogenesis of this condition. However, control studies, prolonged observation and competent interpretation of the changes are necessary before evaluation of such therapy is possible.

Vitamin A Deficiency in Diabetes Mellitus.—Brazier and Curtis observed twenty patients with juvenile diabetes mellitus and found that all of them had poor light adaptation by the Frober-Faybor biophotometer. Three of the group were subjectively aware of night blindness and nine showed cutaneous changes compatible with vitamin A deficiency. The daily administration of 60,000 U. S. P. units of vitamin A, in the form of crystalline carotene dissolved in vegetable oil, for as long as fourteen days did not affect the light adaptation of the patients. The daily administration of 60,000 U. S. P. units of vitamin A, in the form of concentrated fish liver oils, caused the patients' light adaptation to return to normal or nearly normal in from three to twenty-one days. The cause of poor light adaptation in patients with juvenile diabetes mellitus appears to be an inability to convert carotene to vitamin A.

Epidemic Disease of Respiratory Tract.—Reimann and Havens state that in the spring of 1938 eight cases of a severe form of atypical pneumonia were studied at the Jefferson Medical College Hospital; further cases occurred among the hospital personnel in August, November and December. Epidemics of similar disease were observed in Ohio, Delaware, Oregon, New York, Minnesota, Missouri and elsewhere. In January 1939 an epidemic of a mild disease of the respiratory tract began in Philadelphia, which reached widespread proportions in February. Similar outbreaks, with a high morbidity rate, were reported from New York, Minnesota, Illinois, England, France and elsewhere at about the same time. The authors limited their observations chiefly to the interns, nurses and medical students comprising a group of 813 persons, of whom 407 were ill presumably of the same disease. The authors believe that the incubation period is perhaps one or two days, but others have suggested that it is two weeks. The disease was primarily an inflammation of the mucous membranes of the respiratory tract, usually of the nose, pharynx and larynx, occasionally including the trachea and bronchi, and in a few cases the bronchioles and lungs. Constitutional symptoms were usually in proportion to the extent and intensity of the mucosal inflammation. The clinical course was remarkably uniform in most cases, differing chiefly in degree of severity. Nasopharyngolaryngitis was present in 88 per cent of the cases, tracheobronchitis in 6 per cent and tracheobronchopneumonia in addition in 6 per cent. In most of the cases of severe illness the lungs were presumably involved by the infectious agent suspected, without the agency of the

usual varieties of bacteria. There were no serious complications, and all the patients recovered. The disease resembles epidemic influenza in many respects but is caused by a different agent. The disease should perhaps be given a temporary general name such as grip (as dissociated from true influenza) until the etiologic agent is discovered. Many features of the disease, such as its epidemiology, the close resemblance to other diseases known to be caused by filtrable viruses, the normal leukocyte count and the absence of evident causative bacteria, suggest to the authors that a filtrable virus is the cause.

Alcohol Tolerance.—Newman has endeavored to determine whether there is enough individual tolerance to alcohol to affect the validity of blood-alcohol concentration tests. Accepting as a hypothesis that acquired tolerance did occur, the mechanism which might bring it about was determined. A series of dogs was given a test dose of alcohol—first gastrically and after an interval of a few days intravenously. A period of thirteen months was then allowed to elapse, during which time the animals had as their only supply of fluid a 10 per cent solution of alcohol. They drank daily on an average about 7 cc. of alcohol per kilogram of body weight; the equivalent for a man of average weight would be about a quart of whisky daily. At the end of this time the test dose of alcohol was repeated and the curves of blood-alcohol concentration were found to coincide with those obtained before habituation. It is concluded that any tolerance developed by the dogs was not due to either decreased absorption or increased rate of metabolism of alcohol. To determine if tolerance actually did develop with habituation a fresh group of animals was subjected to the test dose of alcohol and not only the blood-alcohol concentration but also the neuromuscular behavior was observed during the period of intoxication. This was judged in nine purely arbitrary degrees. There was a certain divergence in the behavior of the individual dogs at the same blood-alcohol levels, indicating some degree of difference in inherent tolerance to alcohol. The period of habituation was then begun. It had previously been observed that the animals, when given free access to the alcohol solution during the twenty-four hours of the day, soon learned to drink only a little at a time and so never became very drunk. This was remedied by placing the alcohol solution in the cages for only a short period twice a day, with the result that the dogs became very drunk twice a day, while imbibing almost the same daily dose as the previous group. At the end of ninety-seven days they were subjected to the same procedure after the test dose as before. The rate of alcohol metabolism did not show a significant variation from that shown before habituation, but the degree of drunkenness at a given blood-alcohol level showed a consistent and marked decrease after habituation. The results between the abstinent and habituated animals indicate a clearcut acquired tolerance of all animals. That this tolerance is not permanent was demonstrated by its loss after seven months of abstinence. Thus, it is demonstrated that not only do dogs show an individual variation in tolerance to alcohol but the tolerance can be increased by habituation and again decreased after abstinence. If these results with dogs could be applied to the same problem in man, it is apparent that the same blood-alcohol concentration need not indicate the same degree of intoxication in one individual as in another, or even in the same individual should he change his drinking habits.

Acromegaly and Diabetes Mellitus.—Coggeshall and Root discuss the occurrence of twenty-six cases of diabetes among 153 acromegalic patients, evidences of hyperpituitarism with excessive height in three patients among diabetic patients, three frank cases of acromegaly and three of gigantism. The average interval between the onset of acromegaly in the twenty-six diabetic and the three patients with hyperthyroidism and that of diabetes was 9.2 years. A constitutional or hereditary predisposition to diabetes encountered in acromegaly is suggested by the existence of hereditary or familial diabetes in six of the twenty-nine cases, or 21 per cent, whereas among the relatives of the 127 cases of acromegaly without known diabetes only 2 per cent had diabetes. The obesity of 113 patients with acromegaly resembled that of diabetic patients in that 73 per cent of the acromegalic patients had been from 10 to 70 per cent above standard weight. Absence of the specific dynamic action of protein was observed in one case of acute hyperpituitarism at the beginning of a period of diabetic treatment; a subsequent test after treatment showed a normal specific dynamic action. During this period the basal metabolism fell from +34 to +1 per cent. Comparison was made of the weights of organs at necropsy between groups of patients with acromegaly, diabetes, combined acromegaly and diabetes and Simmonds' disease. Splanchnomegaly occurred only in the presence of acromegaly. Its absence in cases of ordinary diabetes argues against the possibility that persistent hyperpituitarism caused the diabetes. The possibility that a brief period of acute hyperpituitarism could produce permanent damage to the islets of Langerhans without splanchnomegaly remains. However, diabetes did not develop in four cases of fugitive acromegaly due to mixed tumors of the pituitary. At necropsy of fifty diabetic patients variations in the size of the pancreas were not associated with variations in the weight of other internal organs, such as was shown at necropsies of patients with acromegaly and Simmonds' disease. The clinical character of the diabetes associated with acromegaly does not show any greater variation in severity, resistance to insulin and duration of life than is seen in a large group of diabetic patients without acromegaly. An inconsistency between a blood sugar curve indicating insulin insensitivity and the fact that the patient had repeated insulin reactions was observed. The usual complications of diabetes including pyogenic infections, arteriosclerosis with gangrene and coronary atherosclerosis occurred. Coma may develop in cases of acromegaly with diabetes and therefore the same careful adjustment of diet and insulin is required as in cases of diabetes of similar severity without acromegaly. In certain mild cases of acromegaly and diabetes excessive polyphagia without loss of weight or development of acidosis resembled the diabetes produced by Young by the injection of anterior pituitary extract. His demonstration that degeneration of the islets of Langerhans and chronic diabetes can be produced in the dog by injection of large amounts of crude anterior pituitary extract of the cow provides a new method of studying the possible production of such changes in the human being with diabetes by such a diabetogenic substance.

Metabolic Effects of Testosterone Propionate.—Kenyon and his co-workers report further studies on the metabolic effects of testosterone propionate on eunuchoidism and compare these effects with those obtained in two normal men and two

normal women. The effect of testosterone by inunction on a eunuchoid was also studied. The results confirm their previous observations: that intramuscular injection, once or twice a day, of 25 mg. of testosterone propionate to a eunuchoid reduced the urinary excretion of nitrogen, sodium, potassium and chloride. A gain in weight was observed, due largely to water held in association with the salts and protein retained. A reduction in the urinary excretion of inorganic phosphorus accompanied that of the other constituents. During recovery sodium, chloride and water were rapidly lost from the body, inorganic phosphorus and potassium less rapidly and less completely, while stored nitrogen was retained in great part for weeks. The two normal young men responded like the eunuchoids, except that the 0.03 Gm. of nitrogen retained daily per kilogram of weight, during the period of maximal effect, was half that of the eunuchoids. One normal young woman responded essentially as the eunuchoids and the normal men. The other woman showed a definite reduction in the urinary excretion of inorganic phosphorus but otherwise distinctly less evidence of a testosterone propionate effect. The reasons for the differences between the women are not clear. The concentrations of urea and non-protein nitrogen of the blood were definitely reduced by such treatment, while those of hemoglobin, plasma proteins and serum sodium, potassium and chloride were unaffected. The reductions in urinary electrolyte excretion in the eunuchoid were unaccompanied by changes in urinary ammonia, hydrogen ion concentration, bicarbonate or concentration of titratable acid. Creatine excretion in the eunuchoid, intensified by ingestion of creatine, was substantially reduced by the androgen and increased during recovery. The daily percutaneous administration of 25 and 50 mg. of testosterone ointment to a eunuchoid produced diminution in the urinary excretion of nitrogen. The basal metabolic rate, fasting respiratory quotient, pulse rate and blood pressure of the normal subjects were not conspicuously affected by testosterone propionate. The basal metabolic rate of the eunuchoid was probably slightly increased; the pulse rate and blood pressure were unaffected. The 102.7 to 252.2 Gm. of protein estimated as retained by these subjects is not accounted for by increases in the bulk of genital tissues and represents deposit of new material elsewhere in the body. This together with the reduction in the urinary excretion of inorganic phosphorus, potassium and creatine points to a somatotrophic influence of androgens and provides a clue to the explanation of unusual body growth accompanying precocious puberty.

Continued Use of Testosterone Propionate.—Eidelsberg and Ornstein cite the effects of the continued administration of testosterone propionate to four hypogonadal males. On several occasions the erections have been too numerous and libido too pronounced. However, decreasing the dose or frequency of injection soon overcame this. Symptoms and signs of masculinity have been proportionately improved. Improvement in general well being and strength was most marked. The mental response and improvement in outlook were excellent. It is the authors' impression after using about 20,000 mg. of the preparation for the four subjects that as yet no real dangers have made their appearance. Several patients have been administering the material to themselves for about one year. It appears that the average weekly maintenance dose may be between 50 and 75 mg., sometimes more or less. The required dose apparently will vary from one patient to another. It seems that the response of the patients with simpler involvement, such as castrates or eunuchs, who were more or less normal originally, may be better than that of other patients, especially if treatment is not delayed too long after the pathologic condition appears. Patients with pituitary disorder (hypopituitarism, infantilism, Lorain-Levi syndrome, Fröhlich's syndrome) will respond better than the older patients from 20 to 30 or more years of age. Occasionally treatment may be discontinued without regression, but usually it must be continued, just as with other endocrine replacement therapy. The potential dangers of unrestricted sale and consequent indiscriminate use become apparent to all interested in the problem. Three of the four patients have since been subjected to subcutaneous implantation of pure testosterone tablets. In each instance the full and dramatic effects of the testosterone propionate, as evidenced by the previous injections, were maintained.

Estrogen and Dysmenorrhea.—Sturgis and Albright used estradiol benzoate (progyon B), 1 cc. of which contained 1.7 mg. (10,000 rat units) of the substance, in the treatment of twenty-five cases of severe dysmenorrhea. The dose was injected intramuscularly every third day. A course of treatment consisted of from three to fourteen injections. The immediate result of a series of such injections depended entirely on how soon in the menstrual cycle the injections were started. If the first of a series of from six to ten or twelve injections was given within the first week after the onset of the menses, the next period was invariably free from uterine cramps. If the series was not started until two weeks after the onset of the previous flow, there was no change in the pains during the subsequent menstruation. Although a completely cramp-free period followed a course of treatment if started early enough in the cycle, the next menses, when no estrogen had been given, was as painful as ever. Endometrial biopsies have furnished evidence that the immediate relief from estrogen treatment depends on the suppression of ovulation. Every biopsy of material taken before a painful period showed evidence of ovulation, whereas every biopsy obtained after treatment and before a period free from cramps showed no evidence of ovulation. When it was possible to take biopsies for three consecutive months it was shown that estrogen treatment for one month did not inhibit or repress ovulation during the next month. Over a period of from six to eighteen months eighty-two courses of injections have been given. In sixty-three of the periods directly following such treatment the patients were free from cramps. An analysis of the nineteen failures shows that in seventeen the injections were not properly timed for the individual case, the number of injections was insufficient or that treatment was given for two consecutive months. A few of the patients studied who have received estrogen on alternate months for at least a year have appeared to show a gradual improvement in the severity of the cramps in the months when no injections were given. It is too early to come to conclusions concerning the permanent value of this therapy. It seems probable that in some of these cases sufficient uterine growth can be produced to result in permanent mitigation of the pain.

Circulation in Athletes.—Stewart and Watson studied the circulation of college athletes between 19 and 23 years of age and compared them with those of eleven normal individuals from 19 to 29 years of age engaged in ordinary sedentary occupations. Measurements were made of the arteriovenous oxygen

differences, oxygen consumption, minute volume output of the heart, vital capacity, cardiac size, circulation time, venous pressure, arterial pressure and heart rate. The results of the study show that, with one exception, there was no significant difference between the measurements of college athletes and those derived from the control group. The stroke volume of the athletes was slightly larger. This difference appears to be related to body size, since the stroke volume per kilogram of body weight and the cardiac index for the two groups are approximately the same.

Decrease of Gastric Secretion with Advancing Years.—To determine whether a gradual decline of secretion takes place in every one or whether some people undergo an abrupt defection while others preserve their gastric juice unchanged into old age, Bloomfield reexamined five normal persons whose gastric secretions were determined more than ten years before. At the reexamination three of the five subjects showed practically identical gastric secretion, one showed slight decline of acidity but not of volume of secretion and one showed a definite decline both of volume and of acid. Why some normal people preserve their gastric secretion unaltered over many years while others show a rapid decline is obscure.

Value of Francis Skin Test in Pneumonia.—Wood treated fifty-one patients with lobar pneumonia caused by type I, II, III, IV, V, VII and VIII pneumococci with antipneumococcus serum and he controlled the dosage of the antibody administered by frequent skin tests with the homologous pneumococcus polysaccharide (Francis skin test). Five patients reacted to the polysaccharide before antiserum had been given. In none of these cases could the Francis skin test be used as a guide to serum therapy. The amount of antibody required to control the pneumonia in the cases studied varied from 11,000 to 1,983,000 units. The author asserts that the use of the test made it possible to treat each patient intensively without wasting antiserum. In every case in which a crisis occurred the Francis skin reaction became positive several hours before or during the fall in temperature. The skin test served as a valuable aid in the early diagnosis of the complications of pneumonia. In every case in which fever persisted in the presence of a positive skin reaction pleurisy with effusion, empyema, meningitis or endocarditis was demonstrated subsequently. No patient survived the pneumonia if a positive reaction failed to develop. Three patients who died reacted positively shortly before death; two died of pneumococcal complications and the third died of uremia, no evidence of active pneumonia being found at necropsy. The Francis skin test was found of value also in determining the optimal dosage of antibody in the treatment of patients who had previously received sulfapyridine.

Prevention of Silicosis.—From his experimental studies as to the prevention of silicosis, Naeslund concludes that: Chemically indifferent dusts such as coal (and even glass) did not bring about any obvious effect on the development of silicotic processes either inhibitive or in any promotive respect (through the enhancement of lymph stasis and the increase of cell aggregations in the silicotic areas). Silicosis and anthracosis appear to develop in the lungs (and lymph glands) quite independently and with no sign of any significant mutual collaboration between the reaction produced by silica and coal (anthracosilicosis). Inhaling alkaline dusts whose main effect presumably consists in a capacity to increase the solubility of silica in the lungs (soda and calcium hydroxide) without silica often caused irritations in the lungs and necrosis with inconsiderable fibrotic response. Similar changes took place after inhalation of these dusts together with silica but there were no direct signs of enhanced toxicity of the silicon in the lungs because these alkali-

line dusts were present. These animals manifested great susceptibility to pulmonary infections which, in early stages, led to death in the silicotic animals. This observation can possibly partly explain certain cases of death from "acute silicosis" among human beings who have inhaled quartz along with alkaline dusts. There was no support to the theory of increased solubility and enhanced toxicity of quartz by the simultaneous inhalation of alkaline dusts. Among dusts which may diminish the toxicity of silica are the positively charged metallic dusts. Of particular interest in this connection is metallic aluminum, which was shown to inhibit the effect of quartz dust. In contrast to the investigations of Robson, Irwin and Denny, complete protection against proliferative fibrosis due to silica was not obtained through the inhalation of metallic aluminum dust. However, it is yet too early to judge whether experimental results will hold good for human beings. Iron and magnesium dust also proved to possess a certain, if slight, inhibitory effect on silica. This effect is not without practical significance, especially in mining where mixed dusts are encountered. Greater attention should be given to the composition of inhaled dusts and to the combined effect of the separate products, as siliceous industrial dust is often mixed. Especially is this advisable when silicosis manifests divergence from what might be reasonably expected.

Artificial Fever and Chemotherapy for Dementia Paralytica.—In comparing the clinical remission rate of dementia paralytica following the various types of treatment, Bennett and his colleagues find that 12 per cent of patients obtained clinical remissions after chemotherapy (tryparsamide) alone, 42 per cent from malarial fever followed by chemotherapy and 53 per cent from combined artificial fever and chemotherapy. Of twenty patients with early dementia paralytica, a full remission was obtained in 65 per cent with partial improvement in 30 per cent. Complete serologic reversal of the spinal fluid was obtained in 40 per cent, with partial reversal in 30 per cent after combined artificial fever and chemotherapy. Of ten patients with dementia paralytica with tabes a full remission was obtained in 50 per cent and a partial one in 30 per cent. The spinal fluid was reversed completely in 40 per cent and partially reversed in 10 per cent. Of twenty-eight patients with advanced dementia paralytica committed to a state hospital, 54 per cent obtained a full clinical remission and 28 per cent a partial remission. A complete serologic reversal of the spinal fluid occurred in 28 per cent and a partial reversal in 50 per cent. Of twelve patients failing to obtain a full remission from malarial inoculation, 33 1/3 per cent obtained a full remission and an additional 25 per

cent were improved following fever and chemotherapy. The spinal fluid was reversed to negative in 33 per cent and improved in 41 per cent. The results from artificial fever, fifty hours above 105 F., combined with mapharsen in the entire group of seventy cases of all stages of dementia paralytica, were full remissions of 53 per cent with an additional 28 per cent improved. A complete serologic reversal of the spinal fluid occurred in 34 per cent, with partial reversal in an additional 37 per cent.

Effect of Amphetamine Sulfate on Sodium Amytal Narcosis.—Myerson and his associates say that in a previous study on the physiologic effects of amphetamine (benzedrine) sulfate they noted that the duration of the narcosis produced by the intravenous administration of sodium amytal was shortened if a subcutaneous injection of amphetamine was given either before or after the sodium amytal. Since then they have studied the effect of the drug given by the intravenous route, thinking that it would be even more effective in counteracting the narcotic effects of sodium amytal. This paper records the quantitative effects of amphetamine sulfate as well as of paredrine hydrobromide, another sympatheticomimetic amine, on the narcosis produced by sodium amytal. They find that amphetamine sulfate is effective in preventing or counteracting the narcosis produced by the intravenous administration of sodium amytal. This action and the fact that amphetamine causes a rapid and prolonged rise in blood pressure may be found useful in certain cases in which it seems desirable to overcome severe side reactions of the narcosis produced by the barbiturates, particularly respiratory embarrassment and pronounced decrease in blood pressure. Paredrine hydrobromide, although closely related to amphetamine, appears to have no effect on the narcosis produced by sodium amytal.

*Lung Abscess. D. D. Matson, Boston.—p. 15.
The Leukemias. H. Jackson Jr., Boston.—p. 22.

Lung Abscess.—Matson concludes that the majority of non-tuberculous pulmonary abscesses follow procedures of the upper respiratory tract or develop subsequent to unresolved pneumonia or other severe infections of the upper respiratory tract. A primary pulmonary lesion is apparently present before secondary infection with mouth organisms takes place; this may be infarction as a result of embolism or atelectasis as a result of bronchostenosis or bronchiolar obstruction. There is no single bacteriologic etiology. The flora of the full-blown abscess is usually complex, and the quantitative importance and possible synergism of the various organisms are not understood. Oral infection is disproportionately common among adult patients with lung abscess of unknown etiology. This type of abscess is rare in infants and children. The diagnosis of lung abscess usually is readily made from the history and general clinical picture, aided by roentgenography and bronchoscopy. The results of physical examination of the chest may be variable and inconclusive. Accurate localization is the most important prerequisite to both medical and surgical treatment. From 20 to 30 per cent of the cases heal with only supportive treatment, and all cases should receive an adequate trial of medical therapy, of which the most important feature is supervised postural drainage. Collapse therapy, either by pneumothorax or by more extensive operative procedures, should never be attempted unless

the abscess cavity has been adequately drained. In peripheral abscess with reaction of the overlying pleura, early external drainage seems to be indicated. In abscesses which fail to respond to medical therapy in two or three months, especially in children whose general condition is good, such radical surgery as lobectomy deserves early consideration in order to avoid progression to chronic pulmonary suppuration and gangrene. The prophylaxis of lung abscess includes careful operative technique, caution in operating on patients with any predisposition to atelectasis, close observance of lung ventilation during and after operation, and conservative surgery on the upper respiratory tract with the use, if possible, of local anesthesia, improved oral hygiene and adequate therapy of respiratory infection in the early stages.

Acne Vulgaris.—Schonberg tabulated the results obtained in 216 cases of acne vulgaris by various methods of treatment. The ages of the patients varied between 12 and 35 years. Questionnaires were sent to many of the patients, and others were seen at the office at intervals of six months after cessation of active treatment. As most recurrences took place from six to twelve months following treatment, a period of fifteen months was the accepted interval to determine the outcome of each case. All patients were treated by indicated local applications before other therapeutic methods were instituted. If no improvement occurred after from four to twelve weeks of local therapy, other methods were employed. Local applications, vaccines and ultraviolet radiation were used for patients less than 16 years of age. Patients selected for roentgen therapy were those with the pustular, large papular and indurated types of acne which had persisted over a long period without improvement under the usual methods of treatment. It was necessary to employ roentgen therapy for 122 patients. The remaining ninety-four were given local therapy and indicated types of internal therapy. These included juvenile acne, seborrheic acne and mild papular acne. Of these, 50 per cent obtained satisfactory results after from one to twelve months of treatment; there were 27 per cent of recurrences from six to twelve months after treatment and these have recently been given roentgen therapy. Seborrheic acne was recalcitrant to roentgen therapy. Patients from 12 to 14 years of age with juvenile acne were resistant to all types of therapy, and methods were used to control rather than to cure the condition. Endocrine preparations were used for twelve patients, and four obtained satisfactory results. In these cases there was evidence of endocrine dysfunction. Of the 122 patients given roentgen therapy eighty-five obtained satisfactory results, thirty-two were improved, five experienced no benefit and fifteen had recurrences. Recurrences following roentgen therapy were due to dietary indiscretions, pregnancy, gastrointestinal disturbances, foci of infection, failure to use astringent preparations for the prescribed periods and sunburn. Roentgen therapy should be preceded by a preparatory course of local therapy for six weeks and if no noticeable improvement occurs roentgen therapy should be instituted. This does not include individuals less than 16 years of age. Temporizing with local measures in recalcitrant cases increases scarring.

Histaminase for Allergic Manifestations.—Forman reports his results with the use of histaminase in the treatment of various allergic manifestations. Enteric coated capsules of histaminase each containing five units of the neutralizing substance were given orally. He finds that histaminase offers a helpful approach to the treatment of urticaria, angioneurotic edema, atopic dermatitis and acute allergic coryza. His results in asthma, contact dermatitis and other allergic conditions were much less satisfactory. It is quite possible that this is a matter of dosage. There were no side effects. Histamine injections and histaminase by mouth are interchangeable in the treatment of allergic manifestations in the skin. In most instances the capsules (one tablet two or three times a day until symptoms disappear) will be more convenient. This preliminary study will have to be extended before conclusions can be reached but the outlook seems most hopeful.

Geographic and Racial Mortality from Heart Disease.—Hedley bases his report on information abstracted from the official mortality statistics issued annually by the United States Bureau of the Census. A downward trend in heart disease mortality among young persons has been noted by several writers. This is corroborated by the author, as he found that death rates from heart disease among persons from 5 to 24 years of age in every section of the country and in every state of the Union in which statistics were obtained showed a decline in the mean annual death rate in 1930-1936 as compared with 1922-1929. The highest mean annual death rates from heart disease among persons from 5 to 24 years of age during 1922-1936 were encountered in the Middle Atlantic states, where the rates were higher than in New England, long supposed to have the highest incidence of rheumatic heart disease. The Mountain and the East North Central states too have a higher reported mortality from heart disease during the age period under study than New England. The Pacific Coast, South Atlantic, West North Central, East South Central and West South Central states follow New England in the order mentioned. Utah, New York, New Jersey, Colorado, the District of Columbia, Pennsylvania, Illinois and Massachusetts had the highest rates, in the order listed. All these states had death rates from heart disease of more than 20 per hundred thousand of population among persons of the ages under consideration during the fifteen year period studied. Mortality from heart disease has continued to decline during the recent economic depression. The death rates from heart disease are higher among Negroes from 5 to 24 years of age in every state and nearly every city in which tabulation according to race is made. This applies to the cities of the North as well as to the cities and states of the South. It indicates a higher mortality rate from rheumatic heart disease among young Negroes. Death rates from heart disease were appreciably lower among white persons of this age group in the deep South than for both races in the Middle Atlantic and New England regions (mostly white) and among the white popula-

tions of most Southern as compared with Northern cities. Rates in cities with more than 100,000 population tended to be significantly higher than in the states and geographic sections in which they are located. This was especially evident in cities of more than 500,000 population. The need for school surveys of heart disease, especially in the South, is emphasized. Studies should be conducted to determine the reason for this apparent decrease in mortality from rheumatic heart disease among young persons, with the view to accelerating further the decline.

Remote Effects of Toxemia of Pregnancy.—Lewis followed for from one to twelve years seventy cases of non-convulsive and thirty-seven cases of convulsive toxemia in subsequent gestations. Of the seventy cases in the nonconvulsive series recurrent toxemia developed in forty-three, eighteen showed no ill effects following the toxemia and permanent vascular renal disease developed in nine. Of the thirty-seven cases in the convulsive series recurrent toxemia developed in eighteen, fifteen showed no ill effects following the toxemia and permanent vascular renal disease developed in four. The duration and severity of the toxemia before the birth of the child seems to be an important factor in the development of permanent vascular renal disease. The age, parity and the degree of hypertension may be of equal importance. However, these factors play a minor part in the convulsive group. Recurrent toxemia may appear in the absence of any detectable sign of renal impairment. The prognosis seems to be more favorable in the convulsive group if the patient survives the initial toxemia. If all patients who have had late toxemia of pregnancy would report for antepartum care as soon as pregnancy is suspected, the incidence of eclampsia would be greatly reduced and the mild forms of toxemia would be discovered and dealt with earlier. A precise knowledge of the time and mode of onset of a toxemia would be helpful in evaluating the danger of continuing the pregnancy. In this way cardiovascular renal disease would not develop in many women at an early age and it would probably be postponed for many years. Antepartum care is imperative if the major risks are to be avoided, especially as the rapid recovery which usually follows one attack gives the patient a false sense of security. The author believes that no woman should be exposed to further risk if she has had two or more toxic pregnancies. Contraceptive advice should be given, as the risks of future recurrence increases with each succeeding pregnancy.

Bacteriophage for Staphylococcal Septicemia.—Longacre and his associates compare the results obtained with bacteriophage in the treatment of thirty-six consecutive cases of *Staphylococcus aureus* septicemia with those obtained in fifty-four not treated with bacteriophage. In their early experiences with bacteriophage the authors used relatively small doses and were not as certain of its potency as they have been more recently. They have therefore divided the cases treated with bacteriophage into two groups: those (fifteen) treated before October 1936 and those (twenty-one) treated for the two years after that date. At this time they not only increased the amounts given but they put their criterion for the potency of the bacteriophage on a much sounder basis. The method for determining the potency of bacteriophage is outlined. The bacteriophages used during the last two years were able not only to clear the culture of the organism in liquid medium but to prevent subsequent growth on a blood agar plate. To this bacteriophage the authors have given the name "double potency phage." The mortality in the early group was 73.3 per cent, in a later group of twenty-one cases it was 28.5 per cent and in the entire group of thirty-six cases it was 47.2 per cent. In the control group of fifty-four cases the mortality was 81.4 per cent. The authors' review of the literature shows the mortality rate of patients with this disease not receiving bacteriophage to be about 80 per cent. The results obtained in this series of cases, especially those in the last two years, make them feel certain that bacteriophage offers a favorable prognosis to patients ill with this disease, if the bacteriophage is of a high potency and if it is given in large doses sufficiently early in the course of the disease.

Acute Appendicitis and Appendical Abscess.—Arnheim and Neuhoef are convinced that death should rarely follow operations for acute phlegmonous or gangrenous appendicitis, appendicitis with local peritonitis or appendicitis with abscess. This view is based on 212 surgical cases in ward service and in private practice from 1931 to 1939. There were four fatal cases, a mortality of 1.8 per cent. Three of the deaths were in cases in which diffuse peritonitis existed at the time of operation. The

fourth death was that of a 73 year old man who had an appendectomy with drainage for acute gangrenous appendicitis. He died on the seventh postoperative day of pneumonia. A post-mortem examination was not performed. The mortality was 0.7 per cent (one death) in 142 cases of acute phlegmonous or gangrenous appendicitis and 23 per cent in the thirteen cases of acute appendicitis with diffuse peritonitis. There were no deaths in forty cases of acute appendicitis with abscess or in seventeen cases of acute appendicitis with local peritonitis. The low mortality (with the exception of that of diffuse peritonitis) is attributed essentially to certain principles in operative technic and in general management before and after operation. Some aspects of diagnosis are stressed, with special reference to abdominal puncture. The choice of time for operation in acutely ill, dehydrated adults is discussed, with emphasis on deferred operation in the presence of proved diffuse peritonitis (proved by abdominal puncture). Avertin with amylene hydrate with the addition of inhalation anesthesia was employed in most cases. Incisions were placed over the known or assumed site of the lesion and were large enough for its complete exposure. Full visualization and isolation of the lesion is a basic feature of the operative technic. In the postoperative management, complicating intra-abdominal suppurative foci are searched for and adequate drainage is provided. Therefore daily (or more frequent) examinations should be made of regions in which complicating abscesses are apt to develop (subphrenic, pelvic, left abdominal). Even when an obvious distant lesion, such as a pneumonitis, may seem to explain the postoperative complication, examination of the abdomen remains an essential step. Reference is made to a study which has shown that suppuration is the most common cause of death after laparotomy for any infective intraperitoneal lesion. Some of the features of the management of appendical abscess which are discussed and on which the results are thought to be based are (1) deferred operation in the early stages of appendical abscess and operation when the acute manifestations have subsided, (2) complete exposure and walling off of the abscess by packs, (3) entry of the abscess through a plane of cleavage, (4) complete evacuation of all recesses of the abscess or abscesses, (5) meticulous technic, (6) removal of the appendix in most instances and (7) drainage of all recesses of the abscessed cavity or cavities by gauze packs and not by tube or rubber dam drains. There were few postoperative complications in the forty cases. A transient fistula to the open stump of the appendix was present in one case. Postoperative incisional hernia did not occur in any of the thirty-one cases followed from one to eight years after operation.

X-Ray Delineation of Articular Cartilage.—A method for the x-ray delineation of articular cartilage without the aid of contrast mediums is described by Rubin. The patient sits or lies on the x-ray table with the outer side of the thigh in contact with a rigid and immobile support placed a few inches above the knee. The knee should be fully extended, the x-ray tube centered above it and a film placed beneath it. The leg is grasped just above the ankle and outward pressure is exerted so as to produce abduction at the knee joint. The pressure should be exerted gradually but firmly, and quite a marked degree of lateral angulation of the knee joint can be produced without the patient experiencing pain. The patient is asked to indicate the point at which the degree of abduction cannot be exceeded without causing him pain. Abduction is not increased after this point has been reached, but the degree of abduction already established is maintained while an anteroposterior roentgenogram of the knee joint is taken. The resulting roentgenogram shows a slight increase in the joint space on the inner side of the knee. But, in addition, the inner part of the true joint space is delineated and appears as a black band of absolute translucency between the articular cartilage of the lower end of the femur and of the upper end of the tibia. It appears white, of course, in the positive print. The articular cartilage of the shoulder and metacarpophalangeal joints are also demonstrable by this method. If there is an effusion in the joint, the outline of the cartilage cannot be visualized. If failure to delineate the cartilage is encountered in a joint in which there is no effusion clinically, it probably indicates that an excess of fluid is nevertheless present in the joint, provided the articular cartilage is successfully delineated in the contralateral joint. Successful delineation of the articular cartilage excludes even a small effusion in the joint.

Lipoid Granulomatosis Without Schüller-Christian Disease.—To demonstrate the existence of lipoid granuloma-
tosis without the Schüller-Christian syndrome, Snapper reports
three cases. The syndrome of Schüller-Christian is only one
special—craniohypophysial—localization of the lipoid granuloma
of the bones. The cases of lipoid granuloma of the bone with-
out craniohypophysial symptoms are probably more frequent
than the well known cases of Schüller-Christian disease. The
characteristics of lipoid granulomatosis are as follows: 1. Mul-
tiple pseudocystic lesions simulate the lesions of von Reckling-
hausen's disease, sometimes even giving the picture of giant cell
tumor or leading to spontaneous fractures. 2. The lesions of
the skeleton are localized only in the pseudocystic and decalc-
ified areas, the cortex is normal elsewhere and the generalized
fibrous degeneration of the bone as seen in von Recklinghausen's
disease is not present. 3. Tenderness of diseased bones is usually
absent. 4. The biochemical changes characteristic of von Reck-
linghausen's disease are absent. 5. A slight hypercholesteremia
is usually present. 6. Areas of typical xanthoma cells (foam
cells) with double refractile cholesterol esters are found in biopsy
specimens. The biopsy necessary for the diagnosis should be
performed on relatively fresh lesions and not in the most exten-
sive areas which have given rise to the most serious symptoms
and signs, particularly fractures. These lesions are usually old
and the lipoid granuloma has been replaced by fibrous tissue
so that only the terminal stage of the lipoid granuloma simulat-
ing fibrous osteitis can be found. It seems possible that the
disease as described by Albright and his co-workers may also
be lipoid granulomatosis of the bones.

Blood Vitamin C Content of Chinese.—The winter vita-
min C content of the blood of five groups of Chinese was deter-
mined by Yu. The first group consisted of eighty-two members
of the house staff of the hospital and medical students. All of
these were supposed to be on a well balanced diet. A small
quantity of fruit was served only in the morning. Oranges,
lemons, grapefruit and other fruits rich in vitamin C were
served infrequently. On the whole, the vitamin C level of this
group was very low, the average being 0.46 mg. per hundred
cubic centimeters of blood. There were only four persons whose
plasma vitamin C content exceeded 1 mg., all of whom took
several oranges or raw turnips every day throughout the winter.
If these four individuals were considered separately, the plasma
vitamin C level of the rest of this group varied between 0.96
and 0.18 mg. with an average of 0.41 mg. All these house
officers and medical students have fairly healthy gums in spite

of the low plasma vitamin C. The second group consisted of
forty-four inmates of the municipal poorhouse. Their average
plasma vitamin C level was 0.2 mg., with a range between 0.12
and 0.38 mg. per cent. The excessively high food prices pre-
vented the inmates from receiving any fresh vegetables during
the winter. At the time when the plasma vitamin C was deter-
mined, they had been eating green vegetables for one month.
The quantity of vegetables given was, however, relatively small.
Although their plasma vitamin C content was extremely low,
all the inmates considered themselves healthy and were able to
carry on their manual work. On the other hand, practically
all of them showed hypertrophied and bleeding gums as seen
in scurvy patients. They had, however, no spontaneous bleed-
ing elsewhere. The third group consisted of thirty-six hospital
patients suffering from various diseases other than scurvy. The
regular hospital diet did not influence the vitamin C content
of the blood of these patients. Their plasma vitamin C content
remained invariably low throughout. The average was 0.28 mg.
per hundred cubic centimeters, varying between 0.11 and 0.42 mg.
No manifest scurvy was present in any of the group. A fourth
group was formed by seven hospital patients, who in addition
to the ordinary hospital diet received extra vitamin C for several
weeks. Their average plasma vitamin C content was 1.2 mg.
per hundred cubic centimeters, the values ranging between 0.58
and 2.13 mg. The fifth group consisted of ten hospital patients
with clinical signs of scurvy. The plasma vitamin C values of
this group before treatment was instituted ranged from 0.1 to
0.23 mg. per hundred cubic centimeters, the average being
0.16 mg. That the low vitamin C content of the blood in the
Chinese is really due to a lack of vitamin C supply and not to
racial differences receives confirmation from the fact that the
vitamin C level of the blood of Chinese goes up immediately if
its supply is increased.

(Naphthylamine, Picrotoxin). M. Koiwa.—p. 163.

Behavior of Blood Platelets in Some Surgical Disorders, with Special
Consideration of Renal Tuberculosis. Y. Yabe.—p. 179.

Modification of Renal Function by Hypnotics.—Koiwa
points out that there is still disagreement about the action of
hypnotics on the diuresis and describes his own animal experi-
ments with several hypnotics. He found that if chloral hydrate
is given in small doses it promotes the diuresis, for it slightly
increases the glomerular filtration and the tubular retroresorp-
tion. However, large doses of chloral hydrate as well as of
barbital and phenobarbital produce a noticeable inhibition in
the diuresis by reducing the glomerular filtration. This inhib-
iting action is most noticeable in the case of phenobarbital.
Stimulation of the brain stem by picrotoxin and by naphthyl-
amine results in a reduction of the glomerular filtration;
moreover, by increasing the percentage of retroresorption in
relation to the glomerular filtration the quantity of urine is
decreased. The author thinks that the reduction of the glo-
merular filtration by picrotoxin is due to the central stimula-
tion of the sympathetic and to constriction of the renal vessels.
The fact that the percentage of retroresorption increases in
relation to glomerular filtration is another factor in the
decreased diuresis. Regarding the action of naphthylamine,
the author says that the decrease in the glomerular filtration
and inhibition in the diuresis which follow the injection of
this substance are due primarily to the constriction of the renal
vessels.

Metrazol Therapy in Nonschizophrenic Psychoses.—

Delmas-Marsalet and his collaborators report on the use of metrazol in twenty-one cases of nonschizophrenic psychoses. Therapeutic response ranged from failure and improvement to cure. Best results were achieved in the ten cases classified under the head of mental confusion, with seven cures and three improvements. In five cases, represented by the manic-depressive type of mental disease, failures predominated over improvements and no cure was effected. In three of these five cases with backgrounds of melancholia and hypochondriac depression the potency of metrazol was so intense as to induce maniacal excitation (in one case by a single dose) and necessitate isolation. In the remaining six cases, representing different forms of delirium, one cure and one improvement are recorded. According to the authors, therapeutic modifications were complicated by the presence of previous mental conditions, such as paranoia. The one cure in this group concerned a woman aged 31, a highly nervous and anxious type, whose delirious onset occurred after normal childbirth. Her condition assumed the form of various accusations of infidelity against her husband and of fears of a poison plot against the life of her child and increased to the point of violent manifestations of anger dangerous to others. After two years she was hospitalized. Altogether three injections of metrazol were given. After the second injection she felt well. A normal condition was reported ten months later. The amount and frequency of dosage and the specific manner of administration in the management of these cases are not indicated. On the other hand, therapeutic effects were observed as early as the first injection in a number of cases. Total doses indicated range from two to twenty injections. At the basis of their procedure lies the theory that certain neurologic and mental disorders spring less from cerebral deficiency than from an altered functional condition that can be modified.

- *Sprain and Luxation of Knee: Definition and Therapy on Basis of Thirty-Nine Cases. R. Leriche.—p. 593.
 Some Surgical Aspects of Kussmaul-Maier Disease (Periarthritis Nodosa). H. Mondor, R. Ducroquet and C. Olivier.—p. 604.
 Treatment of Fractures of Tarsal Scaphoid. P. Lance.—p. 625.
 *Complete Circular Fracture of Cranium Without Functional Disturbances or Cerebromeningeal Lesions. P. Duval and F. Lazard.—p. 643.

Sprain and Luxation of Knee.—Leriche says that the characteristic clinical picture of sprain (edema, local heat, pain and functional incapacity) indicates only functional circulatory phenomena. In observations on thirty-six cases of sprains of the knee and three cases of luxations he emphasizes that there is an essential difference between these lesions. Sprain of the knee is essentially a vasomotor disturbance due to a ligamentous traumatism by forced rotation of the leg against the thigh, most often inside. In its usual type, sprain is without ligamentous laceration and without osseous avulsion. It is cured within a few days by means of anesthetic infiltration of the ligament at the injured and painful points. It is useless to immobilize the member, to make compressive bandages or to massage the part. In some cases the sprain is complicated by ligamentous lesions which involve particularly the cruciate ligaments. They may extend so as to constitute a rupture or an avulsion of the tibial insertion, but an avulsion of a small portion, rarely extensive in volume. The author also has seen chipping of the patellar edge. He never saw, in his thirty-nine interventions, the lesions described as classic on the basis of experimentation on the cadaver, the lesion of Segond and Gangolphe. Regarding the complicated sprains he says that early operation is advantageous in these cases. Luxations of the knee are produced by an entirely different mechanism than are sprains (the body is projected forward while the foot and leg are fixed); they represent luxations of the femur through the tibial collateral ligament. These grave traumatisms produce a veritable dislocation of the knee, which has nothing in common with sprain. It is necessary

to cease confusing the two mechanisms and lesions. They should be strictly differentiated. The luxations of the femur, which are readily reduced because of the enormous ligamentous gap, justify an early operation for repair of the ligamentous damage.

Circular Fracture of Cranium Without Functional Disturbances.—Duval and Lazard report the history of a man, aged 42, thrown from a horse so that the back of his head struck the pavement. He did not lose consciousness and when he arrived at the hospital only a small cutaneous wound was detected in the occipital region. Later he had a mild epistaxis. There were no functional disturbances and the reflexes were normal. After several days the condition of the patient seemed absolutely normal. However, roentgenoscopy of the cranium disclosed a circular fracture, which began in the occipital region at the point of the trauma. It then passed in the lateral and forward directions, traversing the two temporal fossae; its trace was lost in the facial massive; but it seemed to reach the median portion of the orbital fossae and traversed the most anterior portion of the base of the brain, probably at the level of the ethmoid. The discovery of this extraordinary fracture led to a spinal puncture, but the cerebrospinal fluid was found to be entirely normal. The case is noteworthy because the circular cranial fracture caused neither a break in the dura mater nor encephalic changes, which was proved by the absence of clinical disturbances and by the normal condition of the cerebrospinal fluid.

 *Treatment of Painful Amputated Stumps with Synthetic Vitamin B₁. A. Sliosberg.—p. 1589.

Treatment of Painful Amputated Stumps with Vitamin B₁.—Sliosberg reports the results of treatment of painful amputated stumps with synthetic vitamin B₁. Treatment consisted of daily subcutaneous injections of vitamin B₁, mostly 0.01 Gm. Of seventy-four patients eleven were completely relieved, thirty-nine showed considerable improvement, ten moderate and seven slight improvement; treatment failed in seven instances. Results included decreasing intensity and frequency of continued and paroxysmal pain and of cutaneous and reflex phenomena. Examination of the stump revealed decreased cyanosis, equalization of cutaneous heat of the opposite sides and in many cases increase of the circumference of the stump from one half to one inch and decrease of arterial hypertension. Study of the rapidity of action of synthetic vitamin B₁ revealed that completely relieved patients reacted mostly after the first and second injection and that the earlier was the response the better were the final results.

 *Mechanism of Acute Cardiac Pulmonary Edema. S. Wassermann.—p. 402.

Mechanism of Acute Cardiac Pulmonary Edema.—Wassermann reports a case of acute cardiac pulmonary edema in which electrocardiographic records were taken during the attack and during pressure on the carotid sinus, which proved to be therapeutically successful. The electrocardiographic records taken during the attack and during pressure on the carotid sinus do not greatly differ from those made during the interval as regards the rhythm, the beat rate and the conduction; however, the attack electrocardiogram showed a diminution of R₁ and R₂ (perhaps an indication of hypotonia of the cardiac muscle or of insufficiency). This decrease in size in the R wave disappeared when pressure was exerted on the carotid sinus. The success of the pressure on the carotid sinus suggests that the attacks are caused by an insufficiency of the pressoreceptor mechanism. The described case and several similar ones are noteworthy, because the pressure on the carotid sinus produced

only a negligible diminution of the frequency of the pulse (about ten beats a minute); this seems to suggest that pressure on the cardiac sinus during attacks of cardiac pulmonary edema exerts its effects by the vascular reflex rather than by the cardiac reflex. The dyspnea during the attack of pulmonary edema likewise is not regarded as a result of pulmonary stasis but is attributed to pressoreceptor insufficiency. Similarly, the development of alveolar edema is explained not as a sign of mechanical congestion but rather as a sequel of vasopulmonary reflex phenomena, such as vasospasm or vasoparalysis, perhaps increased by capillary permeability. This explains the prompt reversibility of the attacks (spontaneous improvement or by morphine or pressure on the carotid sinus). The pressoreceptor insufficiency may result from (1) anatomic changes in the aorto-carotid region due to sclerosis, syphilis and so on, (2) insufficiency of the left side and the resulting decrease in arterial pressure or (3) a combination of these two factors. The significance of the insufficiency of the greater circulation from the point of view of the pressoreceptor apparatus is discussed.

Iodine in Hyperplasia of Thymus.—In this report Glanzmann is interested especially in the occurrence of hyperplasia of the thymus in the newborn with struma. The struma of the newborn may disappear soon after birth, but frequently it recurs in the course of the first year of life. This type of struma is also frequently accompanied by hyperplasia of the thymus, which, however, does not necessarily produce clinical symptoms. The author reviews the history of a nursing aged 11 months who had a large struma and hyperplasia of the thymus. Iodine treatment counteracted the hyperplasia of the thymus. The author treated a number of cases of mild hyperplasia of the thymus by means of iodine and obtained favorable results. It is possible that the iodine acts by way of the thyroid. This and the close functional relations between thyroid and thymus induced him to use iodine in cases of hyperplasia of the thymus, whether goiter was present or not. He reviews the histories of three nurslings aged 6, 8 and 4½ months in whom hypertrophy of the thymus responded to treatment with iodine. Ointment of potassium iodide (10 per cent) was rubbed daily into the region of the manubrium sterni, but the potassium iodide may be given also in the form of a solution. During the iodine therapy the weight should be controlled and, if there is a loss, the iodine treatment should be stopped.

- *New Method for Rapid Diagnosis of Diphtheria. G. Agnetti.—p. 1684.
- Rehberg's Test for Functions of Kidney. C. Seghini and F. Bazzi.—p. 1707.

Rapid Test for Diagnosis of Diphtheria.—Manzullo's sodium tellurite test for rapid diagnosis of diphtheria was described in *THE JOURNAL*, Sept. 3, 1938, p. 954, and in various Argentine and French medical journals. Agnetti used the test in forty cases in the hospital for infectious diseases at Parma City, obtaining typical positive results in thirty-three cases of diphtheria, atypical positive results in one case of diphtheria, typical negative results in five cases of follicular tonsillitis or Plaut-Vincent's angina and atypical negative results in a case of follicular tonsillitis. Typical positive (or negative) results of the test are clear. Atypical positive results are characterized by the appearance of the black or blackish gray color of the exudates with diffusion of the reaction on the entire pseudo-membrane. Atypical negative results are characterized by the appearance of a pale gray color of the tonsillar follicles. In most of the cases observed by the author the results of the test

agreed with those of the classic laboratory tests. The author concludes that the test is specific for diphtheria and that positive results show the advisability of prompt establishment of serum treatment without waiting for the results of the laboratory tests.

- *Parathyroidectomy in Scleroderma. G. Liuzzo.—p. 41.
- Subacute Circumscribed Cortical Osteitis. C. B. Piana.—p. 50.

Parathyroidectomy in Progressive Scleroderma.—Liuzzo resorted to parathyroidectomy in the treatment of progressive scleroderma in two cases in adults. The disease dated back eighteen and three years respectively. The patients suffered from cold hands and cyanotic fingers before the cutaneous lesions developed. Later they suffered from recurrent formation of abscesses at the distal phalanges, with mutilation of the phalanges in the case of longer duration in which the disease was associated with typical Raynaud's disease. Scleroderma of the face and neck developed in both cases secondarily to the cutaneous lesions on the hands. There were moderate hypercalcemia and sympathetic disturbances in both cases. Bilateral parathyroidectomy was performed in the case of longer duration. In the other case the operation was unilateral. The parathyroids were normal on microscopic examination in both cases. The operation was followed by subjective amelioration. The patients reported a feeling of better elasticity of the skin at the involved regions and of improvement of the local circulation. Calcemia did not change in the case of longer duration and slightly diminished in the other one. The satisfactory results were transient. They lasted for about three months. The author concludes that a dysfunction of the parathyroids may be a factor in the pathogenesis of scleroderma but is neither the main nor the only pathogenic factor, and that parathyroidectomy is not justified in the treatment of the disease.

- *Variations of Nitrogen in Blood After Cerebral and Meningeal Hemorrhage. F. Raggi.—p. 1611.
- Appendectomy with Small Incision: Technic. G. Iesu.—p. 1619.

Nitrogen in Blood in Cerebral and Meningeal Hemorrhages.—Raggi followed the behavior of azotemia in thirty-eight cases of cerebral or else meningeal hemorrhage in persons who had normal kidneys and no history of renal disease in the past. The determinations of nitrogen in the blood were made on the day the stroke occurred or two or three days after and then at intervals of three days for three weeks and of one week for one month. The author found that in all cases of cerebral and meningeal hemorrhage the amount of nitrogen in the blood increases within the first few days after the stroke occurs. Azotemia does not exceed figures of 1 mg. of nitrogen for each thousand cubic centimeters of blood and lasts no longer than a week or twelve days in cases of moderate cerebral lesion from hemorrhage. Hyperazotemia varies within 1.2 and 1.6 mg. of nitrogen for each thousand cubic centimeters of blood and lasts for two or three weeks in grave cases which follow an evolution to recovery and within 2 and 3 mg. in acute cases in which there is grave coma, with death three or four days after the stroke. If death occurs within one or two days after the stroke, hyperazotemia does not appear. The author concludes that the variations of azotemia in cerebral and meningeal hemorrhages are of a prognostic value. With the exception of the cases which follow a rapidly fatal evolution, the more acute the cerebral lesion from the hemorrhage the more grave the evolution of the condition and the higher the figures of hyperazotemia.

- Route of Approach to Intraperitoneal Wounds During War. F. Cuadrado.—p. 267.
- *Sulfanilamide in Treatment of Smallpox. S. Pierna.—p. 279.

Sulfanilamide in Smallpox.—Pierna employed sulfanilamide in cases of smallpox in two different epidemics after the war in Spain. The infection was subacute, acute and confluent in the majority of cases and benign in rare cases. Seven cases are reported. In the majority, treatment began in the vesiculopustular stage. He found that early in the treatment the general

condition of the patients improves. During the first forty-eight hours the fever disappears, the inflammation subsides and the halo of the vesicles becomes pale and then disappears. Coincidentally the vesicle stops growing, turns gray, shows umbilication and becomes an attenuated pustule which dries up in four or five days. The character, form, aspect and fetor of the crusts and their attachment to the skin depend on the acuteness and extension of the disease. In all cases, however, the crusts drop off in from four to six days. In subacute and acute cases, dropping off of the crusts leaves more or less pigmented spots which disappear late after convalescence but never scars. In cases of confluent variola, superficial scars remain. In some cases of acute, subacute or confluent evolution a furfuraceous peeling takes place after detachment of the crusts, which can be controlled by application of sterile ointments on the skin. No complications were observed in the cases in which sulfanilamide was used. The author compared the evolution of the disease with that of a group of cases of benign smallpox in which sulfanilamide was not administered. He found that the vesiculopustular evolution, desiccation and peeling off was accomplished in less than half the time in the sulfanilamide group in comparison to the control group. The scars were deeper and larger in cases in the latter group. The author believes that sulfanilamide attenuates the smallpox virus and that the drug is specific for the treatment of smallpox.

*Multiple Primary Malignant Neoplasms. E. König.—p. 747.

Unusual Fatigue Fractures. H. Muschnug and N. Jannopoulos.—p. 753.

Multiple Primary Malignant Neoplasms.—According to König, Billroth insisted on the following criteria for the establishment of multiple primary malignant conditions: The tumors must vary microscopically as well as in their origin and each, in the end, must give rise to its own metastases. König considers these criteria too strict and is inclined to accept Siebke's view that the necessary conditions are fulfilled if, on a careful study, it has been shown that the tumors in question were not related to one another. The fact that the number of microscopic varieties of carcinoma is rather small does not exclude the possibility of two independent tumors resembling each other microscopically. The metastases do not always follow the structural pattern of the original neoplasm. Important as the microscopic differentiation is for the decision, one cannot rely entirely on it but must take into consideration the anatomic and clinical characteristics of the tumors as well as their response to the treatment. The localization of the tumors is of the greatest importance. The time elapsing between the appearance of two tumors is of limited value. The localization of the second tumor is an important factor in deciding whether it is a metastasis of the first tumor or an independent growth. The age of the patient does not appear to play any part. The incidence of multiple malignant tumors as given in the various statistics vacillates between 1 and 2 per cent of all malignant conditions. The author had ten among a total of 720 malignant conditions (1.4 per cent). The combination of carcinoma and sarcoma is rare. Jolkwer had collected fifty cases up to 1929, to which the author adds one of his own and one of Kreibitz's. More than two dissimilar primary tumors constitute a rare occurrence. The most frequent combination is that of a skin carcinoma with a carcinoma of some other part. The author had four such cases. The question of primary bilateral carcinoma of the breast has been much debated. The incidence was given as high as 5.29 per cent (Gjankowié). The criteria here must be even more strict because of the lymph channels running between the two breasts. König points out the difficulty of regarding the tumor appearing in the opposite breast as a single metastasis because the breast is only exceptionally the seat of metastases. He believes therefore that in the presence of bilateral mammary neoplasms developing at different periods, and in the absence of axillary involvement or any other evidence of metastases, the patient remaining well for years after operative removal of the two, one is justified in considering the second tumor as an independent neoplasm rather than a metastasis of the first.

*Thallium, the New Homicide and Suicide Poison. II. Steidle.—p. 1557.

Thallium Poisoning.—Steidle says that a review of cases in which thallium was used with criminal intent indicates that to some extent thallium seems to have assumed the toxicologic role of arsenic. After one or two days there usually develops a polyneuritis with severe muscular and articular pains, which are localized chiefly in the soles of the feet, the calves of the legs and the knee joints. The patient complains of a furry feeling, formication and hypersensitivity to touch. During the third or fourth week loss of hair sets in, which may lead to complete baldness. Loss of hair in connection with the pains in the legs may be regarded as the characteristic sign of thallium poisoning. General weakness and loss of weight are frequent. The onset of thallium poisoning is sometimes accompanied by vomiting, diarrhea and intestinal colics, which are later followed by constipation. Tachycardia is frequent. The blood picture usually presents an increase in eosinophils, particularly lymphocytes. The urine may contain protein, granulated casts and erythrocytes. The finger nails may show transverse streaks similar to those occurring in arsenic poisoning. Impairment of vision and even complete blindness has been known to occur. Excitation and prolonged insomnia are also frequent. He reviews two cases. In obscure forensic cases it should be a rule to search not only for arsenic but also for the thallium. Thallium can be found in the urine for weeks or months. In the body it is found not only in the blood but especially in the liver, the kidneys and the skeletal musculature. In cadavers it can be detected after years. Among the methods of demonstration, the author regards the spectroscopic one as of greatest importance. It permits the detection of thallium salts if they amount to only 1 part in 100,000. If one drop of such a solution, which contains from 0.02 to 0.03 microgram of thallium, is evaporated in a platinum loop and is then brought into the non-luminant flame, the characteristic light green line can be seen at 5,350.48. The author recommends the spectral analytic method of Bohnenkamp and van Calker for quantitative determinations in forensic cases.

Experiences with Dolantin (1-Methyl-4-Phenylpiperidine-4-Carboxylic Acid-Ethylester), a Spasmodic with Myotropic and Neurotropic Action. E. F. Klein.—p. 1674.

Pathogenesis of Cushing's Syndrome.—Jacobi and Tigges say that Cushing designated the syndrome named "pituitary basophilism" because in eleven of fourteen cases he observed a basophilic adenoma of the anterior pituitary which he regarded as the cause of the disease. This opinion has been challenged, but before they explain their own stand on this problem they report two cases of Cushing's syndrome. The first case was characterized by an increase in the corticotrophic hormone, by hypertrichosis and by hyperphosphatemia from organic phosphorus. In the second case the corticotrophic hormone was likewise increased but there was no hypertrichosis and the hyperphosphatemia was due to an increase in lipid phosphorus. It is noteworthy that in the first case the necropsy failed to disclose an adenoma of the hypophysis but did reveal a hypertrophy of the adrenals with circumscribed adenomas in the cortex. The authors review the leading opinions regarding the pathogenesis of Cushing's syndrome and show that these raise the following questions: Are Cushing's syndrome and interrenalism identical? Is the basophilism primary or secondary? Is the hyperplasia of the adrenal cortex primary or is it the result of an increase in the interrenotropic (corticotrophic hormone of hypophysis) hormone? Can Cushing's syndrome develop without increase in the interrenotropic hormone? The authors assume that the majority of cases of Cushing's syndrome are caused by a functional disturbance in the anterior pituitary with an increase in

the interrenotropic hormone. This excess in interrenotropic hormone leads to an increase in the hormone of the adrenal cortex usually with simultaneous hyperplasia of the cortex and thus to Cushing's syndrome. Less often, when there is no increase in the interrenotropic hormone, the development of Cushing's syndrome is presumably the result of a primary hyperfunction of the adrenal cortex (tumors of the adrenal cortex). The significance of basophilism is still obscure because it has been absent in cases of Cushing's syndrome in which there existed an increase in the corticotropic hormone. Only a careful search for the corticotropic hormone and a comparison with histologic changes will further promote the clarification of the pathogenesis of Cushing's syndrome. Clinical methods will reveal the hormone, not, however, the anatomic changes in the pituitary or the adrenals. The aforementioned explanation of the pathogenesis has therapeutic significance. In a number of cases of Cushing's syndrome, roentgen irradiation of the pituitary has produced good results. The authors believe that the success or failure of this therapy is chiefly dependent on whether or not the rays are applied to the organ in which the primary process exists; that is, if the primary disorder is in the adrenals, irradiation of the pituitary will give no prospect of cure, though irradiation or surgical treatment of the adrenals would do so.

Familial Predisposition for Otitis Media in Scarlet Fever.—Previous investigations on the possibility of familial predisposition for sequels of scarlet fever having produced contradictory results, Gleissner reports studies of 356 cases of scarlet fever at the city hospital in Görlitz from April 1937 to April 1939. These 356 cases amounted to more than 50 per cent of the cases occurring in the entire district, the total number on record for the period being 672. Of the 356 cases of scarlet fever observed at the hospital, otitis media developed in nineteen (5.3 per cent). Eleven of these nineteen belonged to the group of sixty-one cases of scarlet fever from families in which more than one case of scarlet fever occurred, the eleven cases belonging to seven families. Of the remaining 295 cases of scarlet fever observed at the author's hospital, otitis media developed in only eight, or 2.7 per cent. Inquiries disclosed that of the 296 cases of scarlet fever occurring in the same district but not seen at the author's hospital, otitis media developed in eight. The author deduces from these figures that certain families have a predisposition for otitis media as a sequel of scarlet fever.

Fever Therapy in Chronic Enterocolitis.—Lauda and Stritzko report seven cases of chronic enterocolitis in which good results were obtained by means of pyretotherapy. The age of the patients was between 30 and 53. The diseases presented ranged from grave enteritis to ulcerous proctosigmoiditis. In individual cases chronic illness had lasted for from ten to twelve years. Fever therapy consisted of injections of milk, typhus and autogenous vaccines and of blood transfusions. The therapeutic objective of producing high febrility governed the changes from milk to typhus vaccine or from blood transfusion to milk, then to blood transfusion, or from autogenous to typhus vaccine, then to milk and again to typhus vaccine and so on. Almost immediate results could be observed. The seven cases are a part of fifty cases of

chronic enterocolitis pyretotherapeutically managed with good results in half of them. The authors regard fever therapy as contraindicated in septic cases, cachexia and defective circulation. Cases of colitis they found respond better to the treatment than enteritis. Ulcerous colitis, as well as simple enteritis, was benefited.

Vanadium in Treatment of Protozoal Diseases.—Pereira first describes his experiences with vanadium sodium tartrate in syphilis. The salt, in the form of an aqueous solution (0.15 Gm. in 2 cc.), is injected intramuscularly twice weekly. The spirochetes, which could always be demonstrated in the exudate of the primary lesion, disappeared within twenty-four to forty-eight hours and cicatrization was completed in from three to six days. The secondary lesions of skin and mucous membranes likewise disappeared rapidly. Even gummas that had been refractory to bismuth compounds, arsenic and several series of arsphenamine were rapidly cured. The toxicity of vanadium tartrate is low, being tolerated even by children of less than a year. Stomatitis, erythema and hepatic disorders have been observed in rare instances. Because frambesia resembles syphilis, it was decided to try vanadium therapy also in frambesia. The results were favorable.

Hypoglycemic Shock Treatment in Schizophrenia.—Ernst examined the effect of hypoglycemic shock on the circulation of twenty-four schizophrenic patients between the age of 18 and 42. The examinations were carried out with the question in mind whether shock treatment can cause serious circulatory changes endangering life eventually. Readings of the electrocardiogram, frequency of the pulse, blood pressure, product of amplitude and frequency, circulating blood and plasma quantity were examined before administration of insulin and in deep shock. The changes observed were such as one may see in physical labor. The author found no proof of a lasting injury to the heart muscle.

Hereditary Transmission of Congenital Cardiac Anomalies.—Von Knorre began his studies on the hereditary transmission of congenital cardiac defects with fourteen unselected severe cases. As far as possible, studies were made on the siblings, children, parents, uncles, aunts, cousins and grandparents of these patients. In all, 150 persons were examined not only with clinical methods but also with x-rays and, in many instances, electrocardiographic tracings. Case records and postmortem reports were investigated. The author reports

fourteen cases in which, among other defects, pulmonary stenosis, defects in the auricular and ventricular septums, open ductus botalli, congenital tricuspid insufficiency and stenosis of the aortic isthmus were present. He says that, among the persons closely related by blood to patients with severe congenital cardiac defects, mild forms of the same defect were detected repeatedly. These could be explained only in connection with the severe defect of the original patient. Examination with clinical methods disclosed little, but x-ray examination and electrocardiographic studies did reveal defects. The author concludes that extensive familial examinations are advisable in cases of obscure pathologic conditions of the heart.

Monaldi's Suction Drainage of Cavities.—Grass directs attention to Monaldi's method of suction drainage in the treatment of tuberculous cavities. In this method the cavities are punctured through the thoracic wall and a thin rubber catheter is introduced through which air and the other contents of the cavity are constantly suctioned off. Monaldi having employed this method with good results in more than 100 cases, Grass decided to try this procedure on his own patients, the more so since it does not greatly tax the reserve powers of the patient and thus can be employed in weak and in old persons. The method is essentially the application of Bühlau's empyema drainage to the tuberculous cavity of the lung, but it is more difficult in some respects. One of the greatest difficulties is the exact localization of the cavity. The position and size of the cavity must be known in order to determine the site, direction and depth of the introduction of the trocar. The author gives a detailed description of the technic. He thinks that the suction drainage is indicated especially for the treatment of cavities for which other procedures are either too dangerous or not suitable. He reports and discusses the six cases in which he employed the method with good success. He stresses the favorable effects on the general condition and says that his results were essentially like those obtained by Monaldi. In a considerable number of Monaldi's cases the treatment has been completed and in none of them did a fistula remain. In at least half of them a complete success was obtained.

*Myxomas. R. E. J. ten Seldam.—p. 3191.

Tumors of Thymus.—Kouwenaar calls attention to the different hypotheses about the origin of some elements of the thymus, especially the so-called thymus cells. He cites the theories of substitution and transformation. He thinks that this difference of opinion may perhaps explain also why statistics differ so much as to the frequency of thymic neoplasms. He presents a critical analysis of a number of cases that he observed and classifies them as sarcoma, adenoma, carcinoma and thymoma. His report indicates that because of the great differences in structure the classification is difficult but also that true carcinomas of the thymus are rareties.

Myxomas and Malignancy.—Ten Seldam reviews the literature on myomas and then reviews the myxoma material of the cancer institute of the Netherland East Indies. The latter

comprises forty-two cases, namely fourteen fibromyxomas, twelve pure myxomas, two lipomyxomas, ten myxosarcomas, one lipomyxosarcoma and three chondromyxomas. The study of these cases and of the literature convinced the author that all myxomas are to be regarded as potentially malignant. Since irradiation gives little promise of success, the author thinks that every myxoma, including the recurrences, should be treated surgically and as radically as possible.

Pernicious Anemia and Gastric Carcinoma.—A review of the literature regarding the connection between pernicious anemia and gastric carcinoma revealed to Jenner that the opinions of investigators are divided. He studied the fate of 181 patients with pernicious anemia and found gastric carcinoma in eight; but only seven of these can be considered in connection with the subsequent statistical studies. To affirm the relationship between pernicious anemia and gastric carcinoma, it must be demonstrated that the incidence of gastric carcinoma is greater among patients with pernicious anemia than among persons without this disease who belong to the same age groups as do the patients with pernicious anemia. The author made statistical studies, which revealed that the expectancy of gastric cancer among 181 patients would have been less than 0.3. It is important also to determine whether the incidence of gastric carcinoma among the patients with pernicious anemia is still within the limits of accidental occurrence. Accepted tables for statisticians and biometricians indicate that the occurrence of three or more cases of gastric cancer would noticeably exceed the limits of accident. The seven cases thus cannot be ascribed to accident, but a factor must be involved which is responsible for this high incidence. The author reaches the conclusion that the frequent occurrence of gastric cancer in cases of pernicious anemia is due to chronic gastritis, a condition nearly always present in cases of pernicious anemia. Chronic gastritis is the connecting link between the two processes. The author concludes that patients with pernicious anemia should be kept under observation for the possible development of gastric cancer. Carcinomas other than gastric ones do not have a higher incidence in anemic patients.

New Determination of Poliomyelitis Virus in Feces.—Kling and his associates point out that, whereas until recently it was necessary to resort to filtration through candles (Chamberland, Berkefeld and others) to demonstrate the virus of poliomyelitis in fecal matter, Trask, Vignec and Paul seem to have made an advance by substituting for filtration purification by means of volatile antiseptics such as ether or acetone. The authors describe their experiences with this method. In a subject presenting atypical symptoms of poliomyelitis (normal reflexes and absence of paralysis and of disturbances in sensitivity) the new method revealed poliomyelitis virus sufficiently virulent to provoke in monkeys typical experimental poliomyelitis. However, the method has been used in only a small material. It is impossible to give a definite evaluation as yet. The author tested specimens of the same feces after different intervals of storage. A table indicating the results of four different tests reveals that only the portion conserved for twelve hours produced a positive result, whereas the specimens conserved for fifty-three, 152 and 190 hours gave negative results. The authors are unable to say whether the virulence of the poliomyelitis virus is destroyed by the contact with the volatile antiseptic (ether) or by substances in the feces.

STUDIES ON THE MECHANISM OF THE ACTION OF SULFANILAMIDE

IV. THE INFLUENCE OF PROTEOLYTIC PRODUCTS ON THE EFFECTIVENESS OF SULFANILAMIDE

JOHN S. LOCKWOOD, M.D.

AND

HELEN M. LYNCH, M.A.

PHILADELPHIA

Progress in the synthesis of effective chemotherapeutic agents must await a more thorough understanding of the essential mechanism by which sulfanilamide and related compounds produce their effects on bacteria and the lesions associated with infection.

It was because of this that we began three years ago to study certain of the fundamental factors governing the mode of action of sulfanilamide. The data have been obtained from clinical and experimental investigations, since we believe that the problem can be satisfactorily approached only by a concerted and coordinated study carried on by the same group.

An important conclusion reached during a study of 250 cases of human hemolytic streptococcus infections¹ was the fact that sulfanilamide produced its most important effects on diffuse lesions characterized by maximal tissue invasion and minimal tissue destruction. Subsequent investigations have impressed on us the importance of proteolytic products as a rich source of the substances which bacteria may readily utilize in maintaining their biologic activity. These products of protein hydrolysis have been shown by Bradley² to consist of proteoses, peptones, polypeptides and amino acids.

Experiments concerned with the effect of sulfanilamide on experimental hemolytic streptococcus meningitis in the albino rat³ confirmed the clinical observations we had previously made that the drug attacked primarily the invasive component of the infection; in other words, the drug destroyed the bacteria which were multiplying in tissues which were relatively unaltered.

We later reported experiments⁴ in which we were able to confirm the observations of Colebrook and other

workers⁵ on the ability of sulfanilamide in whole human blood to destroy limited numbers of hemolytic streptococci. We observed, however, that phagocytosis was secondary to the humoral effects of the drug. The evidence for this observation, which was not in agreement with that reported by other investigators, strongly indicated that cell-free serum containing sulfanilamide was as bacteriostatic for hemolytic streptococci as whole blood from the same donor. In the course of these studies we recognized the profound importance for bacterial growth in serum of minute amounts of peptone which had been carried over with the bacterial inoculum.

The observations that amounts of peptone as small as 0.01 mg. per cubic centimeter of culture medium had a definite effect on the population curve, with or without sulfanilamide, emphasized the practical inaccuracy of most of the experimental work on the bactericidal action of blood and serum. It was apparent that normal human serum, even without sulfanilamide, was not a favorable culture medium for the multiplication of even markedly invasive strains of hemolytic streptococci. On the other hand, the addition of peptone rendered the serum favorable for the propagation of even relatively noninvasive strains of this organism. The effect of sulfanilamide *in vitro* was only maximal when even small traces of peptone were excluded from the serum. It seemed highly likely that under these circumstances the serum medium was deficient in the readily assimilable nitrogen necessary for biologic activity.

Our data led us to propose as a tentative hypothesis that sulfanilamide interfered with the ability of hemolytic streptococci to utilize protein-split products in serum and that the presence of peptone provided assimilable nitrogen in such excess that sulfanilamide could no longer act with optimal effectiveness. The precise mechanism by which peptone interferes with the action of sulfanilamide is, we believe, necessary for any fundamental understanding of the action of sulfanilamide *in vivo*.

It must be shown that this same phenomenon accounts for the action of sulfanilamide in other mediums and on other types of bacteria. Moreover, such an explanation, if valid, should apply equally to the action of sulfapyridine. In the present paper we present further data on the role of peptone in influencing the action of sulfanilamide on hemolytic streptococci in

human serum and show that the same general principles apply in the action of sulfanilamide on *Bacillus coli* in urine (therapy accounting for Mellon's⁶ phenomenon of "potentiation") and in the action of sulfanilamide on pneumococci and staphylococci in human serum. Furthermore, evidence will be presented to show that peptone has a definite inhibiting effect on the action of sulfapyridine on hemolytic streptococci and, to a much smaller extent, on pneumococci.

TECHNIC

Full technical details have been previously published.⁴ Briefly, the technic employed in all these experiments was as follows: Fresh serum was obtained from freshly

Fig. 1.—Inhibiting effects of varying amounts of peptone on the action of varying concentrations of sulfanilamide (experiment 129).

drawn human blood defibrinated with glass beads. One cc. of serum was placed in each of the required number of small test tubes. We obtained organisms by inoculating 5 per cent horse serum-neopeptone water from stock, incubating it overnight and transferring 0.1 cc. to 4 cc. of 20 per cent horse serum-neopeptone water for a final two hours of incubation. This provided us with an inoculum of young, encapsulated organisms in a logarithmic phase of multiplication. This inoculum was obtained by centrifuging the two hour culture and

resuspending the bacterial sediment in serum. The desired dilutions of culture were then made in serum. This procedure resulted in the exclusion of essentially all the horse serum and peptone from the original medium.

Solutions of sulfanilamide and sulfapyridine were freshly prepared for each experiment by adding the required amount to physiologic solution of sodium chloride and bringing it to a boil. The routine peptone solution was made from neopeptone (Difco) but in some control experiments the solutions were made with other types of peptone. The results were essentially the same. The reagents were added to the tubes of serum with a calibrated micropipet, and in all cases the total quantities of water and sodium chloride were accurately controlled.

As a rule the ratio of added reagents to serum was of the order of 1 to 10 by volume. The tubes were sealed with wood corks dipped in paraffin and mounted on a slowly rotating drum in the incubator. At the desired intervals the tubes were removed and opened and 0.1 cc. was explanted to 1 cc. of neopeptone water in a Petri dish. Ten cc. of horse blood or horse serum agar was added and mixing was obtained in the usual manner. Plates were read after forty-eight hours, the low power objective of the microscope being used whenever necessary. The figure obtained for an average of a number of fields was multiplied by 3,000 in order to achieve the final estimate of population. In all the figures here presented the determinations are based on the logarithm of the population of the 0.1 cc. explant and do not represent any absolute values for bacterial population. It is obvious that any technic of this sort involves fairly wide variations from experimental error. But in view of the fact that the curves are reduced to gross logarithmic representation the experimental error is insignificant.

INHIBITING EFFECTS OF VARYING AMOUNTS OF PEPTONE ON THE ACTION OF VARYING CONCENTRATIONS OF SULFANILAMIDE

Chart 1 shows the population curves obtained with different concentrations of sulfanilamide balanced against different concentrations of peptone. In the upper group peptone and sulfanilamide were added to the test serum immediately after being mixed. In the lower group the sulfanilamide and peptone were incubated together for twenty-four hours before the organisms were added and incubation was started. It was hoped thus to disclose any possible role that might be played by the time factor required for a possible linkage or chemical union between sulfanilamide and peptone.

The following points deserve especial mention:

1. The population curve is raised by decreasing the concentration of sulfanilamide and lowered by decreasing the concentration of peptone. The population curves tend in general to arrange themselves in logical sequence. However, some variations are present, the most conspicuous being the positions of the curves resulting from the addition of 0.1 mg. of peptone per cubic centimeter. The occasional variation from the expected sequence is not unusual in experiments of this type. They are the result of the inherent error of the method.

2. The addition of peptone to sulfanilamide-free control serums produces a marked increase in the rapidity of outgrowth.

6. Mellon, R. R.; Gross, Paul, and Cooper, F. B.: Sulfanilamide Therapy of Bacterial Infections with Special Reference to Diseases Caused by Hemolytic Streptococci, Pneumococci, Meningococci and Gonococci, Springfield, Ill., C. C. Thomas, Publisher, 1938.

3. It is possible through the use of a hundred times as much sulfanilamide as peptone to produce bacteriostasis of an order similar to that obtained in peptone-free serum containing sulfanilamide, even though this small quantity of peptone has a markedly stimulating action on the growth of streptococci in sulfanilamide-free serum (chart 1, upper left corner).

4. There are no significant differences between the groups in which peptone and sulfanilamide were freshly mixed and those in which these substances were incubated for twenty-four hours.

EFFECT OF SULFANILAMIDE ON *BACILLUS COLI* IN URINE

Mellon and his associates⁶ have reported data from experiments on the action of sulfanilamide on *Bacillus coli* in urine. They observed that colon bacilli grown in urine and added, after dilution in urine, to urine containing sulfanilamide were markedly restricted in their growth. If, however, they were diluted in broth

The Effect of Sulfanilamide on Bacillus Coli in Urine (Experiment 112; Mellon's Phenomena of "Potentiation" Explained by Peptone Content)

Broth	Broth	Urine	0	0.1	22	12,000	∞	∞
Broth	Broth	Urine	0.1	0.1	6	400	27,000	∞
Broth	Broth	Urine	0	1.0	13	15,000	∞	∞
Broth	Broth	Urine	0.1	1.0	11	3,000	∞	∞

before being added to the sulfanilamide test urine the inhibition of growth did not take place. In order to account for these variations, Mellon advanced the theory of "potentiation."

According to this concept the organisms were acted on during their phase of growth in urine in such a way as to be rendered susceptible to the action of sulfanilamide in the test urine and in such a way that the "potentiation" of two effects was necessary in order to achieve bacteriostasis of colon bacilli in vitro with sulfanilamide.

The data of Mellon and his associates constitute, we believe, an important confirmation of the theory of protein-split products as inhibitors of the action of sulfanilamide. We have repeated Mellon's experiments, using his own technic. The results are shown in the accompanying table. In the first pair the organisms were grown in urine, diluted in urine and tested in urine with and without sulfanilamide. Of course, no added peptone was present. Under these conditions active growth appeared in the control and marked inhibition, just short of sterilization, took place with sulfanilamide in a concentration of 10 mg. per hundred cubic centimeters.

In the second pair the organisms were prepared in identical fashion except for the addition of a quantity of peptone, so that the final concentration was approximately 20 mg. per cubic centimeter. With the addition of peptone constituting the only difference, no inhibition by sulfanilamide occurred.

In the third pair the organisms were grown in broth, were diluted in urine so as to exclude all except possible traces of adsorbed peptone and were then added to urine with and without sulfanilamide. Under these conditions a definite bacteriostasis took place during the first twenty-four hours, indicating conditions closely resembling those in the first pair; final outgrowth in forty-eight hours did, however, take place.

In the fourth pair the organisms were grown in broth, diluted in broth and added to urine with and without sulfanilamide, after preliminary centrifugation of the broth suspension of diluted bacteria and resuspension of the bacteria in urine. This excluded all the culture medium except for one drop left at the bottom of the centrifuge tube with the bacterial residue. With this preparation there was carried over about 0.1 mg. of peptone per cubic centimeter. Some bacteriostasis resulted.

In the last pair the centrifugation and resuspension were omitted and the result was complete elimination of any inhibition of the bacteriostatic action of sulfanilamide, offering a striking contrast to the preceding experiments.

We believe that Mellon is correct in pointing out that normal urine is not a highly favorable culture medium for *Bacillus coli*. However, it becomes a highly favorable medium if small amounts of peptone or of products of tissue breakdown are present, either in the test tube or in the body. Ballenger and his associates⁷ have recently confirmed the observation that conditions in the urinary tract which might lead to an increased production of products of tissue breakdown may account for failures of sulfanilamide therapy.

In view of the increasing attention which is being paid to the possible action of sulfanilamide as an antiscatalase, it is of interest to call attention to the fact that *Bacillus coli* is generally considered to be highly resistant to the lethal effects of hydrogen peroxide. We merely wish to raise the question whether the latter theory of sulfanilamide action is adequate to explain the action of sulfanilamide on *Bacillus coli* in urine.

EFFECT OF SULFANILAMIDE ON *STAPHYLOCOCCUS AUREUS*: INHIBITING ACTION OF PEPTONE

It has been generally agreed that sulfanilamide possesses little effectiveness in vitro against staphylococci. It is important to point out, however, that the failure to recognize such an effect in in vitro experiments has been due largely to the neglect of the importance of the traces of peptone which would ordinarily be present in mediums in the experiments that have been made. Chart 2 shows the population curves resulting from the inoculation of small numbers of staphylococci into human serum containing varying amounts of sulfanilamide and peptone. The curve to the left indicates that complete inhibition of growth may occur during the first twenty-four hours of incubation if peptone is entirely excluded from the mediums. The presence of as little as from 0.01 to 0.1 mg. of peptone to a large extent overcomes the bacteriostatic effect of even 1 mg. per cubic centimeter (1:1,000) of sulfanilamide. The middle curve shows that sulfanilamide in concentrations of 0.1 mg. per cubic centimeter (1:10,000) is almost completely ineffective in restraining the outgrowth of the same inoculum of staphylococci. The curves at the

7. Ballenger, E. G.; Elder, O. F.; McDonald, H. P., and Coleman, R. C.: Failures in the Treatment of Urinary Tract Infections with Sulfanilamide, *J. A. M. A.* 112:1569 (April 22) 1919.

right in chart 2 compare the efficacy of sulfapyridine and sulfanilamide in concentrations of 0.1 mg. per cubic centimeter (1:10,000).

In these data sulfapyridine is definitely more effective than sulfanilamide in limiting the outgrowth of staphylococci after the first three hours and is slightly more effective in overcoming the growth stimulating effects of peptone. It is our opinion that the failure

Fig. 2.—Effect of sulfanilamide on *Staphylococcus aureus*; inhibiting action of peptone (experiment 132 [Huff]).

of sulfanilamide to influence the course of ordinary staphylococcal infections is the result of the massive tissue injury usually associated with this type of infection. Producing as it often does a local abscess, there is initiated a profound increase in protein catabolism as demonstrated by Daft, Robschit-Robbins and Whipple.⁸ Large amounts of protein-split products such as are present in protein intoxication may, we believe, simulate our experiments in which large amounts of peptone were added. Furthermore, staphylococci grown in serum tend to be resistant to adequate concentrations of sulfanilamide after the action of staphylococcus enzymes has so altered the medium as to render it favorable for staphylococcus growth.

COMPARISON OF THE EFFECTS OF PEPTONE ON THE ACTIONS OF SULFANILAMIDE AND SULFAPYRIDINE ON STREPTOCOCCI

In chart 3 is presented the comparison of the actions of sulfanilamide and sulfapyridine on the population curves of hemolytic streptococci in human serum with and without peptone. When peptone was excluded, the drugs induced similar curves. Both compounds produced sterilization at twenty-four hours, and the curves can almost be superimposed. This is in agreement with data obtained in numerous other experiments, namely that sulfapyridine in vitro is as effective against the hemolytic streptococcus as sulfanilamide itself but in general no more effective. It can be seen from the population curves resulting from the addition of varying concentrations of peptone that the effect of protein-split products is essentially the same for both drugs and that, as far as the streptococcus is concerned, sulfapyridine is no more able to overcome the inhibiting action of peptone than is sulfanilamide.

⁸ S. Daft, F. S.; Robschit-Robbins, Frieda S., and Whipple, G. H.: Plasma Protein Given by Vein and Its Influence upon Body Metabolism, *J. Biol. Chem.* **123**: 87 (March) 1938.

COMPARATIVE EFFECTS OF SULFANILAMIDE AND SULFAPYRIDINE ON PNEUMOCOCCUS TYPE III WITH AND WITHOUT PEPTONE

Chart 4 shows the population curves of pneumococcus type III obtained by the addition of small amounts of sulfanilamide and sulfapyridine to small inoculums of the organisms in human serum. In the one group of experiments peptone was not present in the mediums and in the other 1 mg. of peptone per cubic centimeter was added. The growth in the peptone-free group was not strikingly active during the first five hours, but finally the unfavorable conditions for growth were overcome and rapid multiplication took place. The addition of sulfanilamide so that the concentration became 1:40,000 produced a relatively high degree of bacteriostasis, and at twenty-four hours the population was about 30,000. With the same concentration of sulfapyridine only very few colonies appeared on the plate, and when the twenty-four hour serum medium was transferred to broth no growth occurred, indicating that sterilization had at this time become complete. A similar difference was noted with concentrations of 1:10,000 of the two drugs. Chemotherapeutic activities in vitro were consistent with the differences which are known to exist in the ability of these two drugs to attack the pneumococcus both experimentally and clinically in vivo.

The curves on the right, showing experiments in which 1 mg. of peptone per cubic centimeter was added, show that the higher concentration of sulfapyridine, namely 1:10,000, is to some extent able to overcome the growth stimulating effect of the peptone and to

Fig. 3.—Comparison of the actions of sulfanilamide and sulfapyridine on hemolytic streptococci in serum, with variation in concentration of peptone (experiment 104).

restrict the outgrowth of the pneumococci. With a similar concentration of sulfanilamide very active outgrowth of the pneumococcus took place. This difference between the two drugs in overcoming the growth stimulating properties of peptone may account for the superiority of sulfapyridine in treating pneumococcal infections. It must remain, however, for further study to determine whether or not this is an important factor in explaining the difference in the effectiveness of the two drugs.

THE ROLE OF PEPTONE IN CONDITIONING THE ACTION OF SULFAPYRIDINE ON PNEUMOCOCCUS TYPE III IN SERUM

In chart 5 data are given which further analyze the inhibiting effects of peptone on the action of sulfapyridine on type III pneumococci. In the experiment shown in chart 4 the use of sulfapyridine 0.1 mg. per cubic centimeter made it possible to overcome completely the growth stimulating effect of 0.01 mg. per

Fig. 4.—Comparison of sulfanilamide and sulfapyridine in pneumococcus type III in normal serum, with and without peptone.

cubic centimeter of peptone. That this concentration of peptone was stimulating in its effect on the pneumococcus is shown in the studies made in the control group, in which the rise in population with 0.01 mg. of peptone per cubic centimeter was far more rapid than was true in the peptone-free mediums. Furthermore, in this group the population curves tended to rise proportionately as the concentration of peptone was increased.

It is interesting to note the progressive trend of the curves to move upward, shifting from left to right on these charts, owing to the progressive diminution of concentrations of sulfapyridine. A concentration of 0.01 mg. per cubic centimeter had but little effect on limiting growth even in the absence of peptone. It seems possible to conclude from these experiments that the growth stimulating effect of peptone may be overcome by the presence of a hundred times as much sulfapyridine. This concentration of sulfapyridine is, of course, quite unpractical in view of the low solubility of the drug, unless one is to use the more soluble sodium salt.

COMMENT

In a previous publication⁴ reference was made to the work of Bainbridge, who in 1911 showed that certain bacteria were unable to utilize the complex proteins of egg albumin and blood serum as a source of nitrogen and that when inoculums of the organisms were added to mediums containing these proteins alone the organisms died out. However, when peptones were available in these same mediums bacterial growth was rapidly initiated and, once initiated, continued normally according to a characteristic growth curve. It appeared, therefore, that the bacterium gradually acquired the capacity finally to utilize the more complex protein substrate.

Normal human serum does contain minute quantities of free amino acids and other derivatives of protein catabolism. Since the organisms that are known to be susceptible to sulfanilamide are not in general actively proteolytic, it is reasonable to suppose that when they

are inoculated into blood serum they depend at least in part on obtaining assimilable nitrogen for protein metabolism from previously hydrolyzed protein. Since the concentration of such free amino nitrogen is rarely high it is obvious that the addition of very small traces of peptone may markedly alter the amount of assimilable nitrogen and thus significantly improve the status of the serum as a culture medium for nonproteolytic organisms, such as the hemolytic streptococcus. The fact that effective sulfanilamide action depends on the exclusion of added peptone suggests immediately that the drug must act in some way through interference with the ability of the bacteria to utilize the traces of assimilable nitrogen in whole blood, serum, urine or other body fluids.

It is possible that sulfanilamide combines in some way with the free amino nitrogen of protein degradation products and renders them unsuitable for bacterial utilization. This particular point is still under investigation, but other possible explanations of the precise mechanism involved are also being studied. Such a concept would appear to explain why the sulfanilamide compounds are active only against certain organisms and in certain specialized mediums.

Furthermore, it would explain the failure of sulfanilamide to destroy hemolytic streptococci in localized areas of tissue proteolysis, such as abscesses or heavily traumatized wounds. It would account for the failure of these drugs to act on the localized suppurative lesions of staphylococcal origin and the successful results which have at times attended its use in diffuse staphylococcal cellulitis and bacteremia. This hypothesis is consistent with the spectacular effects of sulfapyridine in pneumococcal infections, because of the minimal tissue injury in the lung in pneumococcal pneumonia.

Fig. 5.—Role of peptone in conditioning the action of sulfapyridine on pneumococci type III in serum (experiment 130 [Rutter]).

SUMMARY

1. Sulfanilamide has a bacteriostatic and limited bactericidal action in vitro on hemolytic streptococci, staphylococci, pneumococci and colon bacilli. The magnitude of this effect is dependent principally on (a) the concentration of the drug and (b) the concentration of "peptone" in the culture mediums.

2. "Peptone," as used in this paper, connotes any product of protein digestion whether prepared artificially in vitro or through the operation of natural enzymatic processes in vivo.

3. It is our belief that sulfanilamide acts by interfering with the nutritional requirements of susceptible bacteria and that the bacteria can die out in a phagocyte-free environment through starvation and autolysis.

4. The addition of peptone to mediums such as serum, which are deficient in nitrogen easily assimilable by bacteria, supplies such an excess of nitrogenous material that the bacteriostatic action of sulfanilamide is to a large degree inhibited.

INTRAVENOUS AND RECTAL ADMINISTRATION OF SULFAPYRIDINE

IN PNEUMOCOCCIC PNEUMONIA

W. L. WHITTEMORE, M.D.

C. L. ROYSTER, M.D.

AND

PAUL A. RIEDEL, Ph.D.

NEW YORK

In the past five months an attempt was made to observe and evaluate any advantages in a series of cases of pneumonia that might result from administering sodium sulfapyridine intravenously and sulfapyridine intrarectally.

In each case the diagnosis was confirmed by x-ray evidence. Preliminary blood culture and typing and culture of sputum were performed in all cases. The blood levels were determined for all patients save those of the oral group admitted later. These are being mentioned without consideration of blood levels.

Eighteen patients were first treated intravenously with sodium sulfapyridine. Of these sixteen were treated entirely by the intravenous route.

Thirteen patients were given sulfapyridine by the rectal method alone and one by the oral and rectal methods combined.

The investigation of the intravenous and rectal routes was decided on in an effort to improve on the results of oral treatment noted in sixty cases, thirty of which have been previously reported. Our hope was to eliminate or decrease nausea and vomiting, a secondary rise in temperature and spread of the disease, occasionally seen after the initial response (whether large or small doses were used), and to hasten recovery.

In our composite temperature chart the intravenous curve is continued only for eighteen hours, primarily showing the rapidity of drop compared with the response to rectal administration.

INTRAVENOUS SODIUM SULFAPYRIDINE THERAPY

In the first two cases, sodium sulfapyridine was given in 1 Gm. doses prepared by dissolving the drug in 1,000 cc. of saline solution. There was a temporary but immediate response, consisting of a drop in temperature of 2 or 3 degrees after one to three hours. The two patients were then placed on oral sulfapyridine therapy and a typical response followed. Although we have given as much as 4 Gm. in 20 cc. of saline solution, making a 20 per cent solution, with no bad reaction, we adopted 2 Gm. of sodium sulfapyridine in 20 cc. of physiologic solution of sodium chloride as the standard initial dose. We found that in sixteen cases this gave an average blood level of 3.7 mg. within five to sixty minutes. In fifteen cases of this group this dose was repeated in four to six hours and there resulted an average blood level of 6.3 mg. After

this second dose fourteen of the patients experienced a drop to normal temperature and an accompanying decrease of toxicity, pulse rate and other symptoms. This response occurred within six to twelve hours after the first dose. A fairly consistent response to treatment was obtained up to this point.

Of the fourteen patients who had received two injections of 2 Gm. each six had no subsequent rise in temperature and had uneventful recoveries. The remainder, on the other hand, experienced recurrences of their fever from twelve to fifteen hours after their second injection, occasionally to a point as high as when treatment was begun, but without as much toxicity. At the time of this reactivation in eight, blood levels in all fourteen cases were found to average 2.2 mg., which indicated a rapid drop.

Further medication produced an elevation in blood level and a favorable lasting response and recovery in five of the fourteen cases. In nine cases when the drug was stopped third and subsequent temperature rises occurred, and again a low level of 1.4 mg. was noted from eight to twelve hours after the last injection, but reintroduction of treatment always terminated the rises. In the cases with this response a widely variable and uneven temperature curve resulted, as was the case with the blood level values. The fact that many patients were found to maintain an adequate blood level for much

Composite temperatures. The solid line indicates rectal therapy and the broken line intravenous therapy.

longer than the twelve hour period described has so far made any set routine impossible beyond the first two doses. In all but six cases we found that the drug concentration was diminished below an effective level at the end of an eight to twelve hour period. The average total dose in this intravenous group was 8 Gm., the smallest 2 Gm. and the largest 20 Gm. No nausea or vomiting occurred except that one patient experienced nausea after each injection.

Of the four patients who did not respond immediately to intravenous therapy,

1. C. C. had type XIX bacteremia and empyema and responded favorably after surgical drainage.

2. C. P., with type I bacteremia and an apparently overwhelming infection, had a blood level of only 3.2 mg. in spite of having received 18 Gm. of sodium sulfapyridine in thirty-six hours. He was given 200,000 units of type I serum on account of his low blood level and persistently positive blood culture, had interlobar empyema after leaving the hospital and was treated by repeated aspiration.

3. From T. J., aged 49, thought to have streptococcal pneumonia because of the sputum culture and the clinical course, type I pneumococcus was recovered by terminal lung puncture. His death will be discussed later.

4. F. D., with type VII pneumonia, whose temperature remained elevated for thirty hours, received 10 Gm. intravenously in 2 Gm. doses every six hours during the period. When the blood level reached 4 mg. a favorable response occurred and recovery was uneventful, including the subsidence of jaundice, which was present on admission. The ieteric index decreased from 12 to 6 at the same time. A similar reduction of the ieteric index was observed in five other patients, none of whom had clinical jaundice.

RECTAL SULFAPYRIDINE THERAPY

Fourteen patients who did not appear too ill on admission had rectal treatment alone, and all recovered. Sulfapyridine was initially administered in 6 Gm. doses suspended in 3 ounces of water with from 0.66 to 1 Gm. of sodium bicarbonate. This formed an effective non-irritating suspension of the drug. After a cleansing enema this suspension was introduced as a retention enema. At four hour intervals 2 Gm. doses and later 3 Gm. doses were employed. Blood levels were lower than those obtained by the oral and intravenous methods and averaged for the group 3.0 mg., though patient F. C. reached a concentration of 5.4 mg. It was found that three times the usual oral dose was required to produce adequate blood levels. The clinical response was slower than with the oral route but was uniformly satisfactory. The average time required for the temperature to reach normal was forty-eight hours, as compared with thirty-six hours in those treated orally and twelve hours in those treated intravenously. The same decrease in toxicity was also noted. Only one patient, F. C., exhibited nausea and vomiting. No evidence of rectal irritability was noted. Therefore we believed that the rectal route, with the dosage as outlined, is a satisfactory and less disturbing method for patients showing gastric irritability and not too seriously ill.

THE SEVEN FATAL CASES IN THE SERIES OF NINETY-TWO CASES WITH ORAL, INTRAVENOUS AND RECTAL TREATMENT

1. J. G., aged 53, had type III pneumonia. Blood culture yielded negative results. Oral treatment was begun thirty-six hours after onset and death occurred on the fifth day. On the fourth day the blood level was 14.0 mg. total, 13.3 mg. free; on the fifth day, 14.5 mg. total, 9.0 mg. free. The white cell count was 27,000 with 68 per cent polymorphonuclears and 30 per cent band forms. This patient was admitted in poor condition and showed no favorable response.

2. T. J., an alcoholic man aged 49, mentioned previously, was admitted on the fifth day of illness with a pulse rate of 136 and respiratory rate of 36, in a markedly toxic and delirious state. He received 8 Gm. intravenously in twenty-four hours, which produced a blood level of only 2.4 mg., but the temperature was normal forty-eight hours after the initial dose. The pulse remained rapid, and the patient continued to be toxic. With another abrupt rise in temperature intravenous administration of 2 Gm. was followed by normal temperature persisting throughout his last forty-eight hours. His sputum cultures were reported to contain chain cocci, but a terminal lung puncture showed type I pneumonia. Though this patient died afebrile and in vasomotor collapse with a rapid running pulse, we feel that he should have had the benefit of heavier dosage.

3. A. O., a desperately ill alcoholic man aged 60, was admitted on the fifth day of illness. There were type II organisms in the sputum, and the blood culture was positive. The pulse rate was 160 and the liver enlarged. He died twenty-four hours later. He received 2 Gm. intravenously every two hours for five doses without response. The blood level was 6.1 mg. total and 3 mg. free.

4. R. S., a man aged 74, was delirious and comatose on admission, with a large liver, jaundice and a temperature of 104 F. He was given sulfapyridine orally, and the temperature,

pulse and respiration were normal for three days. Then the temperature fell to between 95 and 96 F. Clinically he was much improved. He died suddenly with normal temperature six days after admission. Autopsy showed resolving pneumonia and toxic hepatitis, the cause of which was not definitely determined. He had had 34 Gm. of the drug in all.

5. McG., a man aged 36, had type II organisms in the sputum and a positive blood culture. He was admitted on the seventh day and died five days later. He had 23 mg. of sulfapyridine in all. He became progressively more toxic. On the twelfth day he had 200,000 units of type II serum. The white cell count was 17,000 with 83 per cent polymorphonuclears and 10 per cent band forms. Death occurred in vasomotor collapse.

6. C. D., a man aged 40, was admitted on the seventh day of illness with type I organisms in the sputum, a positive blood culture and empyema, which was evacuated on the eighteenth day. Death occurred on the fifty-first day. Autopsy showed acute vegetative endocarditis, pneumococic meningitis and chronic empyema. The total dose (oral) was 44 Gm. in fifty-one days, but of this 30 Gm. was given in the first week. Five blood levels varied between 2.6 and 7.2 mg. (total). A violent allergic reaction occurred after 30,000 units of serum was given, though conjunctival and cutaneous tests had been negative.

7. K., a woman aged 76 with type XII pneumonia, was admitted in coma. She had an initial favorable response for three days but died on the sixth day. She had sustained a head injury ten days before admission, which may very well have been the primary factor in her death.

SUMMARY

Ninety-two patients were treated with sulfapyridine and its sodium salt, with a mortality of 7.6 per cent. Of this number fourteen were treated intrarectally and eighteen with sodium sulfapyridine intravenously. Although this is too small a number to be of value statistically, certain facts are apparent and inferences may be made concerning the value of these forms of treatment. Rectal administration almost eliminates nausea. Blood levels tend to be lower, and response to therapy is slower.

The intravenous use of sodium sulfapyridine in the manner described caused no local or systemic reaction. Nausea occurred after injections in only one case. The therapeutic effect was rapid save in the four cases considered in detail. There was difficulty in maintaining constant blood levels, and a consequent erratic course of recovery was found to be the chief difficulty in this form of treatment. Seven deaths occurred in ninety-two cases and were analyzed. We are of the opinion that, when there is no initially favorable reaction to sulfapyridine, serum should be used in full doses.

From a study of response and blood level, we are of the opinion that a desirable method of administering these drugs to seriously ill patients is to give sodium sulfapyridine intravenously at first and follow it immediately with sulfapyridine administered orally.

The Keynote to Sir William Osler's Character.—It has been said that he would have achieved greatness in any career, but it is certain that in no other walk of life would he have found so much exercise for his many gifts or fulfilled himself and been so happy as in the practice of medicine. His intense sympathy, his genius for friendship with young and old, his capacity for teaching and organization—for all these medicine gave ample scope. The keynote to his character was struck in a remark he made to his students: "There are people in life and there are many of them whom you will have to help as long as they live. They will never be able to stand alone."—Langdon-Brown, Sir Walter: *Thus We Are Men*, New York, Longmans, Green & Co., 1939.

SULFANILAMIDE IN TREATMENT OF
SORE THROAT DUE TO HEMO-
LYTIC STREPTOCOCCI

WITH CONTROLS

PAUL S. RHOADS, M.D.

EVANSTON, ILL.

AND

M. L. AFREMOW, M.D.

CHICAGO

In a previous study¹ it was found that approximately one fourth of the illness among the nurses under our care was due to tonsillitis and pharyngitis. Two thirds of these cases were caused by hemolytic streptococci. While this incidence of sore throat may be slightly higher than that in a similar age group of the general population, it is probably lower than the incidence among children. Because of the great frequency of this condition it is likely that as much sulfanilamide is administered for sore throats proved or presumed to be due to hemolytic streptococci as for any of the great variety of infections for which it seems to be useful. The medical literature abounds with reports on the use of this drug for hemolytic streptococcus pharyngitis and tonsillitis. Many workers report almost uniformly favorable results.² Others, while impressed with results of the use of sulfanilamide in other streptococcal infections, have noted little favorable effect in ordinary hemolytic streptococcus tonsillitis and pharyngitis.³ Coburn and Moore⁴ found that sulfanilamide administered to rheumatic subjects after the onset of streptococcal throat infections did not prevent recrudescences. However, in a series of eighty rheumatic children who were given the drug prophylactically seventy-nine escaped hemolytic streptococcus infection and signs of activity of rheumatic infection. Schenck,⁵ in a review of the use of the drug in otolaryngology, points out that most observers report favorable clinical responses to the drug but that the carrier state was usually not much affected. In our search of the literature we were unable to find a single study in which there were adequate controls.

Our own series is not large but may be of some value because the sulfanilamide treated patients were compared in as many respects as lent themselves to statistical analysis with a group being treated under identical conditions but without this drug.

The present study was begun two years ago. The subjects were all nurses of Cook County Hospital and Evanston Hospital who contracted hemolytic streptococcus pharyngitis or tonsillitis while on duty. There were occasional accompanying infections of the nasal

passages and sinuses—five among the sulfanilamide treated group, six among the control group. Only patients with severely inflamed throats, proved to harbor beta hemolytic streptococci and with fever, were selected for the study; alternate patients were treated with the drug. Of the thirty-one sulfanilamide treated patients only three had a temperature below 100 F. and all but five had exudate on the mucous membranes of the pharynx or tonsils. In the control series of thirty-six cases five had a temperature below 100 F. and all but four had exudates. Many patients originally in the treated series were excluded from the study because treatment was begun after the fifth day of illness or because the drug had to be stopped because of reactions before a therapeutic effect could be expected. Aside from the use of sulfanilamide the patients of the two groups were treated in exactly the same way, i. e. with rest in bed until the temperature had been normal at least three days, hot alkaline gargles and either codeine or acetylsalicylic acid for aching in the body. The patients were not given sulfanilamide until their cultures had been reported positive for hemolytic streptococci, so that on the average treatment was begun 2.8 days after onset. The average duration of sulfanilamide treatment was 5.6 days. The dosage varied slightly according to the

TABLE 1.—Comparison of the Clinical Course of the
Sulfanilamide Treated Group with the Group
Receiving No Sulfanilamide

tolerance of the patients for the drug, but the average daily dose was 3.6 Gm. (54 grains). On the first day from 5 to 6 Gm. (75 to 90 grains) was given, divided usually into four doses. After that from 0.6 to 1.0 Gm. (10 to 15 grains) was given at four hour intervals through the day until the drug was discontinued. The average blood level attained was 6.38 mg. per hundred cubic centimeters. Apparently our method approximated that used by Long and Bliss in a series of forty-six cases.⁶ In their series, on the average treatment was begun 2.3 days after onset and the average duration of treatment was five days. These workers state that "a blood concentration of 4 to 6 mg. per cent of sulfanilamide is generally all that is needed, and in many instances the infection may be controlled with lower levels of the drug." They consider the proper dose for adults to be 1 Gm. (15 grains) every four hours day and night at the start. After one day of normal temperature they cut this dose in half, then rapidly decrease as convalescence is established. Long states that none of his treated patients had complications.

RESULTS

Table 1 shows that in our study the clinical course of the sulfanilamide treated series was practically identical with that of the untreated controls. The complications of the sore throats in the two groups were also almost the same. A striking feature of pharyngitis and tonsillitis due to hemolytic streptococci is the profound

asthenia which so often incapacitates the victims for many days after the fever, cervical adenitis and other objective signs of active disease have subsided. This complication was much more frequent in our sulfanilamide treated group, possibly as the result of treatment. Those patients found to have positive cultures for hemolytic streptococci two weeks or more after the initial infection are listed in the series as "carriers." It will be seen that sulfanilamide did not influence the carrier state, there being eleven carriers in each group.

Cervical adenopathy occurs to some degree in nearly every case of streptococcic pharyngitis and tonsillitis. It is not considered a complication by us unless the adenopathy is thought to prolong the disability an unusually long time or unless suppuration occurs. Hence cervical adenitis does not appear as a complication in the tabulation of either series.

Severe mental depression.....	1
Total number exhibiting toxic signs (cyanosis not included) 16	

REACTIONS TO SULFANILAMIDE

Some degree of cyanosis was observed in practically every case in which full doses of sulfanilamide were administered and was not listed as a toxic reaction in the tabulations. Table 3 shows that sixteen of the thirty-one sulfanilamide treated patients had one or more of the usual reactions to this drug. Nausea and vomiting were the most frequent reactions; leukopenia, precordial pain and hallucinations were the most alarming. These reactions subsided after withdrawal of the drug. Several other cases are not included in this series

because severe toxic manifestations led to discontinuance of the drug before an adequate amount could be given.

SUMMARY AND CONCLUSIONS

In our series of thirty-one sulfanilamide treated patients and thirty-six controls treated under similar conditions but without sulfanilamide, this drug was not found to reduce the severity of the symptoms, shorten the period of incapacity, reduce the incidence of complications or reduce the duration of the carrier state. Toxic manifestations of the drug other than the usual cyanosis occurred in one half of the cases in which sulfanilamide was administered. In a few instances these reactions were serious enough to cause genuine concern.

It is not wise to make sweeping generalizations on the basis of one series of controlled cases. Sulfanilamide is a drug of proved value in severe infections of deep structures due to the hemolytic streptococcus. However, in the average uncomplicated case of tonsillitis or pharyngitis due to hemolytic streptococci the advisability of its routine use is questionable. Certainly no physician should be censured for withholding the drug in these conditions unless complications such as severe cervical adenitis, paranasal sinusitis, otitis media, mastoiditis or meningitis supervene.

THE PRODUCTION OF SULFAPYRIDINE RENAL CALCULI IN MAN

FOLLOWING ADMINISTRATION OF SULFAPYRIDINE

NORMAN PLUMMER, M.D.

AND

FREDERICK McLELLAN, M.D.

NEW YORK

The great interest in the therapeutic use of sulfapyridine has brought forward a multitude of reports showing its efficacy in acute infections. These articles have been closely followed by observations on the toxic manifestations of the drug; apart from gastrointestinal disturbances and a tendency for blood destruction, emphasis must be placed on the effect on the kidneys.

In view of the fact that most of the absorbed drug is excreted by the kidneys, either in the pure or in the conjugated form, it is conceivable that, if precipitating factors are introduced, serious traumatic or mechanical effects might be produced. That crystals of sulfapyridine are precipitated in the kidney tubules and pelvis in certain species of mammals has been shown by many observers.

Antopol and Robinson¹ were the first investigators to report the appearance of uroliths in monkeys, rats and rabbits following the oral administration of large amounts of sulfapyridine. These investigators also described changes in the kidneys and ureters secondary to the deposition of sulfapyridine crystals and stones. In the milder cases they found a simple calculous ureteritis and pyelitis causing hematuria, but in the more severe cases marked pyelonephritis producing definite nitrogen retention in the blood. The sulfapyridine stones were discovered to be nonopaque to x-rays, and of particular significance was their observa-

tion that the concretions when not excessive were later redissolved or washed out. Gross, Cooper and Lewis² analyzed the urinary stones occurring in rats after sulfapyridine administration and found that they were composed of 6.4 per cent free sulfapyridine and 64.1 per cent acetylsulfapyridine. Toomey,³ in a communica-

the other by pyelographic study in which crystals and concretions of sulfapyridine were found also in the urinary bladder. A brief description of these cases already has been reported, but because of the interest in this material we are making a more detailed presentation.

REPORT OF CASES

CASE 1.—History.—R. L., a married woman aged 40, was admitted to the Medical Pavilion of the New York Hospital Dec. 27, 1938, with weakness, fatigability, afternoon fever, loss of weight and anorexia of three months' duration.

At the age of 3 years the patient had inflammatory rheumatism involving the knees, ankles and wrists. Cardiac murmurs were detected after this illness, and from that time physical activities were always restricted. At the age of 8 there was a recurrence of inflammatory rheumatism.

Examination.—The temperature was 38.2 C. (100.8 F.), pulse rate 94, respiratory rate 18, and blood pressure 105 systolic, 60 diastolic. The patient was poorly nourished. The middle finger of the right hand in the region of the middle phalanx was swollen but not discolored or tender. No other joints were involved. The patient was in no particular discomfort and was not dyspneic or orthopneic. The heart was slightly enlarged. A short systolic thrill was felt at the apex. A soft, rough systolic murmur was heard best at the apex, and a crescendo presystolic murmur was heard, loudest in the mitral area. The liver and spleen were easily palpable but were not tender.

Urinalysis showed a specific gravity of 1.008 and no albumin or sugar. Microscopic study showed no red blood cells or casts but a few white blood cells. The hemoglobin content of the blood was 80 per cent, red cell count 4,000,000 and white cell count 7,500. Serologic tests were negative. Blood culture yielded a nonhemolytic alpha prime streptococcus.

Course in the Hospital.—On the basis of the physical features and the positive blood culture, the diagnosis of subacute bac-

Fig. 1 (case 2).—Excretory pyelogram taken fifteen minutes after the dye was injected. A calculus, nonopaque to x-rays, is in the pelvis of the left kidney. Also there is evidence of hydronephrosis and delayed excretion. This study was made three days after sulfapyridine therapy had been instituted and twenty-four hours after the sudden appearance of hematuria and of pain in the left flank. Only 11 Gm. of the drug had been taken when this reaction occurred.

tion to THE JOURNAL, described confirmatory experiments and suggested the dangers of sulfapyridine urolithiasis in the human being.

Hematuria in the human being following sulfapyridine therapy has been reported by a number of investigators.⁴ The occurrence, in addition to hematuria, of renal colic and nitrogen retention in human cases was described first by Southworth and Cooke⁵ and more recently by Tsao, McCracken, Chen, Kuo and Dale.⁶ The patients described by the latter investigators were children, one of whom died of uremia developing after sulfapyridine therapy.

In a recent report we⁷ described the renal complications occurring in 323 cases treated with sulfapyridine. In this series there were three cases of nitrogen retention, four cases of hematuria without proved stones and two cases of hematuria in which there was sulfapyridine calculous formation, in one proved at autopsy and in

Fig. 2 (case 2).—Pyelogram made fifteen minutes after the dye was injected, showing a normal left kidney. The calculus and evidence of hydronephrosis no longer appear. This study was made twelve days after the attack of hematuria and colic.

terial endocarditis was made. The patient was given sulfanilamide 1.2 Gm. six times daily until a total of 55.2 Gm. had been given. This drug was discontinued and sulfapyridine was administered in doses of 1 Gm. six times daily, and until shortly before death 555 Gm. had been received. The sulfanilamide had had no clinical effect on the patient, but with the sulfapyridine the temperature was reduced, and in spite

of some nausea the patient was much more comfortable. The blood cultures at several examinations were sterile and at all times showed a colony count lower than on admission. The blood hemoglobin level was slightly reduced, but at no time did it go below 70 per cent. The urine showed a few white blood cells and eight days before death showed a large number of

Fig. 3 (case 2).—Pyelogram made seventy-nine days after the reaction, again showing a normal left kidney.

red blood cells but no gross blood. The blood sulfapyridine varied from 4 mg. to 9 mg. per hundred cubic centimeters. On the one hundred and sixteenth hospital day the patient suddenly had convulsive seizures and lapsed into a stupor. Later there developed a stiff neck and a positive Babinski sign on the right side, and lumbar puncture revealed an increased pressure and grossly bloody spinal fluid. The course was rapidly downhill, and the patient died on the one hundred and seventeenth hospital day.

Postmortem Examination.—In the pelvis of the right kidney there were found numerous petechiae and in one calix a colorless stone with a rough surface, measuring 0.5 cm. across. Around this stone were two very small soft sandy crystalline masses. The urinary bladder contained no stones or concretions. When crushed on a slide and examined microscopically, the stone was seen to be made up of coarse rough wedge-shaped striated colorless crystals of which the base and one side were straight, while the third side was ragged. The point was usually sharp. A qualitative test for sulfapyridine was positive. A quantitative test⁸ showed the stone to be composed of about 97 per cent sulfapyridine. The difficulty of solubility was such that all acetylated sulfapyridine was transformed into the free form in accomplishing solution, so that the proportion that was originally free was not determined.

CASE 2.—History.—K. K., a man aged 46, Greek, was admitted to the medical pavilion April 28, 1939, with pain on respiration in the right lower part of the chest and cough with pink sputum. The symptoms had been present for eighteen hours and a chill occurred shortly before admission. The past history was irrelevant.

Examination.—The temperature was 40.2 C. (104.4 F.), pulse rate 120, respiratory rate 36 and blood pressure 140 systolic, 62 diastolic. The patient was flushed and slightly dyspneic.

Physical signs, confirmed by x-ray study, revealed pneumonia of the right lower lobe. The remainder of the physical examination was noncontributory.

Urinalysis showed a specific gravity of 1.020, acid pH, no sugar or albumin and no cells on microscopic examination. The red blood cell count was 4,500,000 with the hemoglobin content 98 per cent; the white cell count was 12,600. The sputum yielded pneumococcus type III. The blood culture was negative. The Wassermann reaction was 4 plus.

Course in Hospital.—The patient was given the usual supportive measures for pneumonia, and sulfapyridine was administered orally 2 Gm. as an initial dose and 1 Gm. every four hours. There was rapid improvement in the chest condition. Forty-eight hours after admission the patient complained of severe pain in the left flank and passed bloody urine. He received 11 Gm. of sulfapyridine prior to this attack, and the drug was promptly discontinued. The blood sulfapyridine determination was too low to read. An excretory pyelogram on May 1 (fig. 1) showed delayed function in the left kidney with hydronephrosis and a negative shadow in the renal pelvis. A plain roentgenogram of the abdomen did not show any evidence of opaque calculus. Owing to the persistent pain, cystoscopy and retrograde pyelography were done May 3. Cystoscopy revealed the trigon covered with whitish masses of tiny crystals, and a clot protruding from the left ureteral orifice was also studded with crystals. These crystals were washed out for examination and a catheter was easily passed 25 cm. to the left renal pelvis. The urine specimen from each kidney contained no crystals. The function of the left kidney was markedly reduced in urea and phenolsulfonphthalein output as compared with that of the right kidney. The pyelogram again revealed the negative shadow in the left renal pelvis. There was a definite diminution in urinary output for four days. The renal pain on the left persisted for eight days;

Fig. 4 (case 2).—Sulfapyridine crystals (magnified) washed from the urinary bladder.

crystals were not found in the urine after the sixth day, but hematuria persisted until the eighth day. An excretory pyelogram May 12 (fig. 2), fourteen days after the initial attack, revealed a normal left kidney without a filling defect. Results of urinalysis were normal. The lung by this date was clear, and the patient had been afebrile for five days. He was followed at weekly intervals and remained asymptomatic. An excretory pyelogram July 15 (fig. 3), two months after the attack, again showed a normal left kidney.

⁸ This examination was made by Dr. Jacob Farth.

⁹ These tests were made under the direction of Dr. Ralph G. Sullivan.

*Laboratory Report on Crystals Found in the Bladder.*²—Examination of the crystals revealed small irregular friable white masses. Microscopically these were made up of rather easily broken up bundles of long pointed wedge-shaped, sometimes notched, colorless crystals. On treatment with acid and azotization they gave a typical reaction for sulfapyridine. Morphologically these crystals resembled the crystals from a kidney (case 1) which were identified as sulfapyridine (fig. 4).

SUMMARY AND CONCLUSIONS

1. Two patients had renal calculi after sulfapyridine treatment, proved at postmortem examination and by pyelography, respectively. Both patients had hematuria and one also had renal colic. One had had only 11 Gm. of the drug and the other 555 Gm.

2. Pyelograms in one of the cases showed calculi, nonopaque to x-rays. The serial study indicates that later the calculi dissolved or were washed out and the kidney function returned to normal.

3. The features of these two cases, together with the experimental studies reported by other investigators, indicate that hematuria and other urinary symptoms occurring after sulfapyridine administration are caused by the deposition of sulfapyridine crystals and concretions in the kidneys and ureters.

4. Frequent examinations of the urine, particularly for red blood cells, should be made during sulfapyridine therapy. The drug should be withheld or given very cautiously if hematuria occurs or if the patient is known to have a diminished kidney function.

SULFANILAMIDE IN THE TREATMENT OF CHANCROID

W. F. SCHWARTZ, M.D.

PASADENA, CALIF.

AND

HAL E. FREEMAN, M.D.

CLEVELAND

Since sulfanilamide was first found to be of value in hemolytic streptococcal infections, the question of ascertaining its action in infections caused by the hemophilic streptobacillus of Ducrey suggested itself.

Previous to the present writing, reports on this subject, all of which have been encouraging, have come from three British clinics¹ and from one American group.² Since we have available a large hospitalized venereal service, it is felt that our experiences are worthy of record.

Sulfanilamide has been used in the treatment of chancroid at the Cleveland City Hospital since July 1937. This report covers a series of thirty-seven cases, which were very carefully selected and were considered suitable for this study. For comparison there is also presented, as a control group, a series of sixty similar cases, most of which were seen before July 1937, and which were treated by other methods.

From the Department of Dermatology and Syphilology of the Cleveland City Hospital, service of Drs. H. N. Cole and J. R. Driver, and Western Reserve University School of Medicine.

2. Kornblith, B. A.; Jacoby, Adolph, and Wishegrad, Michael: Treatment of Chaneroid with Sulfanilamide, *J. A. M. A.* 111: 523 (Aug. 6) 1938; Sulfanilamide in Treatment of Chaneroid, *New York State J. Med.* 39: 364 (Feb. 15) 1938.

CRITERIA FOR SELECTION OF CASES

No patients were included if the diagnosis was purely clinical.

All patients with buboes and with positive Frei and chancroidal intracutaneous tests were eliminated unless there was a history and/or a scar of a previous bubo to account for the positive Frei test, and also unless a tissue smear was positive for *Bacillus haemophilus* of Ducrey.

Also eliminated from the reported series were all cases of chancroid complicated by early infectious syphilis. This was done because even though dark field examination was negative the possibility still remained

LESION	SERIES	S	P	DAYS REQUIRED FOR HEALING				
				10	20	30	40	50
BUBO, unruptured	CONTROL	M	13	[Healed by Day 25]				
	TREATED	M	2	[Healed by Day 25]				
BUBO, ruptured	CONTROL	M	5	[Healed by Day 55]				
	TREATED	M	3	[Healed by Day 25]				
ULCER not situated on glans penis	CONTROL	M	30	[Healed by Day 60]				
	TREATED	M	12	[Healed by Day 25]				
ULCERATION of glans penis	CONTROL	M	7	[Healed by Day 175]				
	TREATED	M	3	[Healed by Day 25]				

Results of treatment. S indicates sex and P the number of patients.

that part of the lesion could be an unrecognized chancre which might heal rapidly as a result of specific anti-syphilitic therapy and thus invalidate the reported results.

In order to compare our results with those of previous authors, our cases are divided into those with and those without buboes. The latter group has been further divided into cases with lesions on the glans penis and those with lesions on other dermal structures. This division was made because lesions on the glans heal much more slowly than those in other locations. Whether or not the buboes were ruptured made considerable difference in the time required for healing in the control group, so cases with bubo in the treated series were again classified as those with ruptured and those with unruptured buboes.

DOSEAGE

Various daily doses were used and evaluated. The average for the total group was 46 grains (3 Gm.) a day. The total dose varied between 280 and 950 grains (18 and 62 Gm.) and averaged 642 grains (42 Gm.) per patient. After the initial dose of from 3 to 4 Gm. the maintenance dose was determined by the clinical response and of course by the weight and age of the patient. Toxic symptoms such as dermatitis, purpura and cyanosis were carefully watched for, and total blood counts and blood sulfanilamide determinations were frequently done (at least twice a week) in order to guide the maintenance dosage. It became apparent that a high maintenance dosage is of the utmost importance. The least desirable combination is a low initial and a low maintenance dose. The next least desirable is a high initial and a low maintenance dose. The low initial and high maintenance combination is more desirable, while the high initial and high maintenance combination is the most desirable if proper precautions, such as blood study and alkalization, are taken to avoid toxic reactions.

The results observed, according to the previously mentioned various types of lesions, are incorporated in the chart and are self explanatory. The graph indicates days required for healing in each instance and does not represent the total period of hospitalization.

It is noteworthy that the duration of the disease before admission to the hospital varied between two and 365 days and averaged for the control group thirty-five days and for the treated group thirty-two days.

The diagnostic period varied between one and twenty-seven days and averaged two days for the control group and slightly more than five days for the group treated with sulfanilamide. This longer diagnostic period for the latter group indicates that more careful study was made of them in order to be sure they were proper cases for evaluation of the action of the drug. In order to observe the results further, the treated patients were hospitalized for an average of more than six days after complete healing had occurred and they were dismissed for further observation as outpatients.

RESULTS

The results observed in this hospital compare favorably with those reported elsewhere as "dramatic" or "all healed within two weeks." Including all the various types of lesions, the average period of time required for healing in the control group was slightly more than thirty-two days. For the sulfanilamide treated group, this time varied from seven to twenty-three days and averaged 15.7 days, in comparison.

Chancroidal ulcers situated elsewhere than on the glans penis respond best to treatment.

Chancroidal bubo, unruptured, is next most responsive.

There is little difference in the response to sulfanilamide of chancroidal bubo, ruptured, and of ulceration of the glans penis, but the latter lesion is slightly less responsive.

CONCLUSIONS

Sulfanilamide has well known toxic possibilities and therefore should not be used in a routine manner for chancroid without careful control. This drug is efficient, even in resistant cases, and if carefully controlled can be used with gratifying results.

261 East Bellevue Drive—Cleveland City Hospital.

THE USE OF VITAMIN B₁ FOR THE RELIEF OF PAIN IN VARICOSE ULCERS

ALTON OCHSNER, M.D.

AND

MARVIN C. SMITH, M.D.

NEW ORLEANS

Whereas varicose ulcers of the lower extremity are usually accompanied by itching, burning and aching,¹ relatively infrequently is the pain severe. Occasionally, however, patients with varicose ulcers are seen who complain bitterly of pain which is little affected by the usually successful therapeutic methods. Because we have secured such splendid results in these cases by the administration of vitamin B₁, this presentation is made.

For some time, in the Department of Surgery at Hutchinson Memorial Clinic of Tulane University, all patients with clinical and subclinical avitaminosis, persistent neuritis and painful chronic lesions have been given vitamin B₁ (thiamin, Betaxin). It was striking that patients with painful varicose ulcers were relieved shortly after the institution of the vitamin B₁ therapy.

Krieg² had previously (1938) reported results obtained with the use of thiamin. Of the thirty-five patients with varicose ulcers treated with thiamin alone, all but five experienced relief of pain. Four of the five had severe venous stasis and induration of the veins and surrounding areas. Pain, stiffness, heaviness and pressure usually were relieved from four to eight days after the institution of the treatment. When treatment was discontinued, the symptoms returned but in milder form. Krieg observed that in twenty-one cases there was a definite decrease in the size of the varicosities in that the veins, even the large ones, became smaller and that this decrease was visible as well as measurable. Merdinger³ also observed the beneficial effects of thiamin in relieving the symptoms of varicose ulcers but stated that the relief was of only short duration and did not occur in every case. He believed that better results were obtained when the vitamin was administered intravenously. Krieg⁴ in reply to Merdinger's report stated that according to his experience small oral doses were effective in relieving symptoms and, in fact, this method of administration was so satisfactory that the use of intravenous injections had been abandoned.

Of ten patients with painful varicose ulcers admitted to the Hutchinson Memorial Clinic and treated with vitamin B₁, all but one were definitely relieved and eight had complete subsidence of their symptoms. The length of time before the onset of relief varied from three to eleven days, with an average of five days. In two cases the symptoms completely subsided in four days. In the other six cases, disappearance of the symptoms was more gradual but progressive. In five of the ten cases there was, in addition to the relief of symptoms, definite improvement in the healing of the ulcer, although there had been more or less resistance to therapy prior to the vitamin administration. In two cases the discontinuance of the vitamin resulted in the recurrence of the pain but in a milder form. It was promptly relieved when the vitamin was again administered. One patient who had used sedatives for four years because of pain associated with her varicose ulcer has been completely relieved since the institution of the vitamin therapy. The one patient who had no symptomatic response had a large indurated and infected ulcer of four years' duration.

All the patients were women varying in age from 27 to 75 years. There was no correlation between the age of the patients and the onset of relief.

Patients were instructed as to diets relatively high in vitamin B₁ content, but as there were no means of checking these diets accurately the adequate intake of vitamin B₁ was assured by the administration of thiamin tablets in doses above the daily minimum requirement of 300 international units, or 1 mg.⁵ It is known that vitamin B₁ is stored in the body in small amounts, but until clinical tests are perfected by which the amounts stored can be determined quantitatively the adequate dose necessary for these patients can be determined only by the trial and error method. Rather early in our investigation it became evident that large doses of the vitamin B₁ were necessary to produce the desired

results. At the present time investigations are being made concerning the relative values of oral and intravenous administration.

Krieg used daily intramuscular injections of from 5 to 10 mg. of thiamin until improvement was noted, then gave 1 mg. three times a day by mouth for a week, followed by a week's administration of 1 mg. twice daily, and then a week's administration of 1 mg. once daily.

It has been suggested by Goodhart and Jolliffe⁶ that the best results in the treatment of alcoholic neuritis were obtained by the use of large daily doses (as much as 50 mg. per day) rather than continued small doses. Weiss⁷ has shown that when no clinical improvement resulted from the use of small doses of vitamin B₁ in the treatment of alcoholic neuritis the use of larger doses brought about definite clinical results. These experiences, as well as our own, suggest that large doses of vitamin B₁ are necessary in order to relieve pain both in alcoholic neuritis and in varicose ulcer. At the present time we believe that at least 5 mg. (1,500 units) three times a day should be given patients with painful

Summary of Cases of Varicose Ulcers Treated with Thiamin

Case*	Age	Duration of Ulcer	Symptoms	Mg. of Thiamin per Day	Onset of Relief
1	75	2 weeks	Burning pain	3	5 days
2†	37	8 months	Itching, heaviness	3	11 days
3†	49	10 months	Pain	15	5 days
4	27	2 years	Cramping pain	15	4 days
5	41	3 months	Severe burning	3	5 days
6	65	1 month recurrent 24 years	Itching, heaviness	30	Some in 4 days
7	46	2 years recurrent 4 years	Pain	3	None
8	61	2 years	Pain	15	7 days
9	37	2 years	Burning pain	15	3 days
10	31	2 months	Severe pain	3	3 days

* All patients were women.

† Medication was discontinued temporarily with return of the original symptoms in a milder form. Symptoms ceased when medication was resumed.

varicose ulcers, and if the symptoms do not subside within three to four days the dose should be doubled.

There is no contraindication to the giving of large doses over prolonged periods. Experiments on animals have shown that enormous doses can be administered with no ill effects. However, lethal doses have been obtained in experiments on animals.

The explanation for the relief of pain associated with varicose ulcers when large amounts of vitamin B₁ are administered is not simple. Because of the inability to determine quantitatively the amount of vitamin B in the blood, one is unable to demonstrate a vitamin B deficiency. Because of prompt relief of pain following the vitamin administration, it is possible, however, that these patients did have a vitamin B₁ deficiency and that the relief was occasioned by correction of the deficiency. The vitamin deficiency may be due to inadequate supply, inadequate absorption or inadequate utilization of the vitamin in the diet. On the other hand, if the supply is normally adequate, the deficiency may be due to factors which require an abnormal amount to supply the body's needs.

RECOVERY IN ANYOTROPHIC LATERAL SCLEROSIS

TREATED WITH TOCOPHEROLS (VITAMIN E):
PRELIMINARY REPORT

I. S. WECHSLER, M.D.

NEW YORK

Amyotrophic lateral sclerosis is a chronic disease involving essentially the old and new motor systems, namely the anterior horn cells and the pyramidal tracts. The disease, which affects older adults and persons past middle age, is regarded as a degenerative one of unknown etiology. It is relentlessly progressive. It generally begins in the upper extremities with loss of power, atrophies and fibrillations, and when it ascends, as it generally does, to the medulla it terminates fatally. The duration is from one to two years, longer if the disease begins in the lower extremities. As far as is known there are no remissions, there is no treatment and there is no cure. The neurologic characteristic of the disease is a combination of paralysis and atrophy with increased deep reflexes. In every other disease in which the anterior horn cells are affected, the deep reflexes are invariably lost in the affected limb. In amyotrophic lateral sclerosis, because the pyramidal tracts are also involved, the reverse is true. Because of its insidious nature, the patient at first pays no attention to the disorder or is treated for a long time before it is recognized. This is the reason why the neurologist rarely sees early cases. When they come to him they are usually fairly well advanced. This is of great importance.

The following two cases are reported because they are the first instances within my personal knowledge in which amyotrophic lateral sclerosis has yielded to treatment.¹ The results of treatment have been so spectacular thus far that I am constrained to make this preliminary report. Experimental work on animals has shown that once the anterior horn cells are destroyed because of vitamin privation they cannot be repaired, and the degeneration is progressive. If, however, the condition is recognized early and treated promptly there is the possibility not only of arresting the process but of reversing it. This points to the need of treating amyotrophic lateral sclerosis in its early stages before irreversible damage is done.

The treatment of amyotrophic lateral sclerosis with vitamin E, more particularly the alpha-tocopherol factor, was undertaken with the following considerations in mind: It has been known for a long time² that the privation of vitamin E will cause atrophies and paralyses in young rats. The paralyses were observed in the course of experiments on sterility. More recently (1935) Ringsted³ reported on paresis in old rats suffering from chronic avitaminosis. A year later (1936) Lipshutz⁴ described degeneration of the nervous system as the result of privation of vitamin E. In 1937

From the Neurological Service of the Mount Sinai Hospital.
Read at a staff conference of the Mount Sinai Hospital, Jan. 8, 1940.
1. Since this work was done there has appeared an article by Franklin Bicknell entitled Vitamin E in the Treatment of Muscular Dystrophies and Nervous Diseases (*Lancet* **1**: 10-13 [Jan. 6] 1940) in which recovery is reported in two cases of amyotrophic lateral sclerosis, one of six years' duration. Essentially the article deals with the dystrophies, and neither is made of tales.

2. Evans, H. M., and Burr, G. O.: Development of Paralysis in the Suckling Young of Mothers Deprived of Vitamin E, *J. Biol. Chem.* **76**: 273-297 (Jan.) 1928.

3. Ringsted, Axel: A Preliminary Note on Appearance of Paresis in Adult Rats Suffering from Chronic Avitaminosis E, *Biochem. J.* **29**: 788-795 (March) 1935.

4. Lipshutz, D.: Les voies atteintes chez les jeunes rats manquant de vitamine E, *Rev. neur.* **65**: 221-233 (Feb.) 1936.

Burr, Brown and Moseley⁵ further reported on paralyzes in old rats on a diet deficient in vitamin E. In 1938 Einarson and Ringsted⁶ published their monograph on the effects of chronic vitamin E deficiency on the nervous system and on the skeletal musculature in old rats. They showed that the posterior columns and pyramidal tracts as well as the anterior horn cells and possibly those of the intermediolateral gray were affected in vitamin E privation. They raised several interesting practical and theoretical questions, among them the fact that the pyramidal tract in the rat is situated in the dorsal and not the lateral column of the spinal cord. What is pertinent to our discussion is that they demonstrated degeneration of the pyramidal tract and anterior horn cells and spoke of the analogy to amyotrophic lateral sclerosis in man.

While it was known that vitamin E privation can cause paralyzes of muscles, it was not known what the antisterility factor has to do with it. Einarson and Ringsted raised the question whether there was not also another factor, the privation of which caused degeneration within the nervous system. Thanks to the work of Evans and his collaborators,⁷ it has become known more recently that whole wheat germ oil contains alpha and beta tocopherols and that the alpha probably has to do with the muscular atrophy. It was at this point that I began treatment of amyotrophic lateral sclerosis with a synthetic preparation containing alpha-tocopherol.

REPORT OF CASES

CASE 1.—A. L., a man aged 52, an insurance agent, complained of loss of power in the left hand and tiredness of the legs. He was perfectly well up to the present illness, although he stated that he had had an occasional tingling feeling in the left forefinger and aches in the left scapular region for years. In July 1939 he began to have weakness of the left hand, the loss of power gradually becoming so marked that he practically lost the use of the hand. About a week or so before coming to the office, on Oct. 18, 1939, his legs began to tire. There were no other complaints: no fever, no visual disturbances, no gastrointestinal symptoms, no urinary disturbances, no loss of libido, no history of trauma, no major or even minor illnesses.

Neurologic examination was entirely negative except for the following: The biceps, triceps and wrist jerks were much more active on the left than on the right, the left knee jerk was greater than the right and the left abdominals were weaker than those on the right, but the ankle jerks were equal and there were no pathologic reflexes. The left plantar reflex was not present. There was marked weakness of the fingers of the left hand, partial left wrist drop, and weakness of the muscles of the forearm and shoulder girdle. There was marked atrophy of the small muscles of the hand, the interossei and the thenar and hypothenar eminences. The paresis was flaccid. A few fibrillations were seen occasionally in the left arm and shoulder muscles. There were no sensory disturbances. The cerebral nerves were entirely normal. There was asymmetry of the facies with slight lagging of the left corner of the mouth, actually of no significance as the patient had it all his life.

The patient had been receiving vitamin B therapy with no effect. He was admitted to the Mount Sinai Hospital, where all the neurologic observations were confirmed. The serologic reactions were negative. The spinal fluid was normal and there was no block. The blood was normal. X-ray examination of the skull, chest and cervical spine showed no patho-

logic condition. The electrical reactions, despite the marked atrophies, were not conclusive. A short time before coming to the hospital the patient was given whole wheat germ oil. As soon as studies were completed he was given two tablets of ephynal, 3 mg. each, three times a day. Improvement began almost immediately. After a few weeks the patient regained sufficient power to button his coat, make his tie and use his hand in eating. The wrist drop began to clear up. Once he ran out of the medication and did not take the tablets for three days. Weakness began to return, but immediate recovery set in once more on resumption of treatment. Four weeks later I purposely stopped the administration of the tablets for five days and again the weakness returned, only to disappear as soon as the tablets were readministered. At present he has good power in his hand, and the interosseous spaces and the thenar and hypothenar eminences are beginning to fill out.

CASE 2.—C. B., a woman aged 36, a housewife, was admitted to the hospital in August 1939 with the complaint of weakness in both arms and legs of one year's duration. At first there was difficulty in walking; soon the hands and arms became so weak that she could not feed herself; much later dryness of the throat and difficulty in swallowing set in. There were no visual disturbances, no impairment of urinary function and no other complaints. For years the patient had eaten few green vegetables.

The positive neurologic observations were fibrillations in the muscles of the extremities, trunk and tongue, and marked atrophy and loss of power in the muscles of the hands, feet, and tongue and some of the arms and legs. All the deep reflexes were hyperactive and there was bilateral clonus. The spinal fluid, including dynamics, was normal, and so were the blood chemistry and the serologic reactions. X-ray examination of the spine was negative. There was no doubt of the diagnosis of amyotrophic lateral sclerosis.

The patient was given vitamin B and a diet fairly rich in all vitamins. Within one month she appeared to feel subjectively better and the fibrillations seemed less. In October she was given the tocopherol acetate, three tablets of 3 mg. each in addition to the vitamin B. The difficulty in swallowing gradually subsided by the time of her discharge in November. When seen one month and two months later, the atrophy and fibrillations of the tongue had disappeared and her general strength increased to the extent that from being confined to bed she could walk with assistance; indeed she returned to the follow-up clinic of the hospital.

COMMENT

Although only two cases are cited, the prompt response to vitamin E, namely the synthetic tocopherols, seems to me to be of unusual significance. It is of great importance that full recovery occurred in an early case and that the atrophy of the tongue, which was the youngest symptom in the older case, yielded soonest. Trial in three other cases in which the condition is very far advanced have thus far yielded no results; in a fourth there seems to be some recovery of muscle power. This is in accord with what has been observed in experimental animals. Of even greater significance is the fact observed on two occasions, when the administration of the tocopherols was stopped, that the weakness returned, and, when treatment was resumed, recovery promptly resulted. This is almost a crucial physiologic and clinical experiment indicating that the recovery was the direct result of the treatment.

There are a few theoretical questions worth considering. One is the fact that aside from the pyramidal tract and anterior horn degeneration there is also involvement of the posterior sensory columns in the experimental animals of Einarson and Ringsted. Posterior column degeneration does not as a rule occur in amyotrophic lateral sclerosis, but it so happens that I *

reported cases in which there was posterior column involvement. Another point is that the pyramidal tract in rats is not quite comparable to the pyramidal tracts in man. It would therefore be necessary to try vitamin E privation in higher animals, particularly the macacus. Experiments are being undertaken with monkeys deprived of vitamin E, and treatment with wheat germ oil and synthetic tocopherols will be instituted.

There seems to be good evidence of the relation of vitamin E privation to the dystrophies. The muscle degeneration in dystrophy differs from the atrophy which is secondary to loss of anterior horn cells. It is possible, in view of the disappearance of cells from the intermediolateral horns of the cord, that the trophic sympathetic nerves may have something to do with the dystrophies. In any case treatment of the dystrophies with vitamin E is definitely indicated in the hope of curing early cases and arresting old ones.

Although the relapse in case 1 after withdrawing the synthetic vitamin E and the prompt recovery after readministering it is almost absolute proof of the efficacy of the treatment, more cases will have to be treated before final answer can be given. The treatment is now being carried out on a large series and further reports will be made. It is of interest, first, that ordinary good diet may be deficient in vitamin E, that some persons for various reasons do not partake of those articles of diet which are rich in vitamin E, and that some individuals have gastrointestinal disturbances before the advent of the disease. This points to the probability of malabsorption despite adequate vitamin E in the diet. Indeed one patient gave a history of abdominal distress and restricted diet for a year preceding the onset of the illness. This parallels more or less the condition in vitamin B privation, which results in neuropathies. It will therefore be necessary to obtain good dietary histories in every case, particularly as to likes and dislikes of foods. This too is being carried out in the new cases under observation.

In view of the fact that there is or seems to be poor absorption from the gastrointestinal tract in cases of amyotrophic lateral sclerosis and that one cannot in any event gauge the amount that is absorbed, the need of administering vitamin E parenterally becomes extremely important. One can now inject the tocopherol in oil intramuscularly, and in the new group of cases injections will be given in addition to feeding of synthetic vitamin E and whole wheat germ oil. Comparative results will be reported as soon as they are available.

CONCLUSION

I would not be understood to say that the absence of vitamin E alone is the cause of amyotrophic lateral sclerosis. There is a theoretical possibility that it is, but we have as yet no proof. It is quite possible that other unknown factors play additional etiologic roles. All one can say is that in one case of amyotrophic lateral sclerosis complete recovery was brought about by the administration of tocopherols, and in another there was marked improvement. I should add that although the patients were also given vitamin B they did not show recovery and that other patients to whom shotgun prescriptions of the A, B, C and D vitamins were administered did not respond. Experimental animals treated with the vitamin B alone also failed to respond. But there is some reason to believe that the added administration of vitamin B may aid the vitamin E in treatment.

THE HOUSSAY PHENOMENON IN MAN

REPORT OF A CASE OF DIABETES MELLITUS,
INFARCT OF THE ANTERIOR LOBE OF
THE PITUITARY BODY AND TER-
MINAL HYPOGLYCEMIA

J. H. KOTTE, M.D.

AND

A. R. VONDERAHE, M.D.

CINCINNATI

The regulation of carbohydrate metabolism by certain endocrine glands, notably the pancreas and the hypophysis, has been known for some time, but the complex interrelationship between them is as yet imperfectly understood. The antagonism between the pancreas and the hypophysis is perhaps the best appreciated phase of this activity; however, certain other endocrine glands, notably the thyroid and the adrenal glands, also have a regulatory effect on carbohydrate metabolism. The internal secretion of the pancreas is known to be antidiabetic and to aid in some manner the utilization of dextrose by the tissues; the anterior lobe of the hypophysis, however, possesses a diabetogenic or gluconeogenic principle. It was Houssay's¹ publications on the close relationship between the pancreas and the hypophysis that served to stimulate the accumulation of a great mass of experimental data, most of which supports his work.

The Houssay phenomenon refers to (1) the hypersensitivity of hypophysectomized animals to insulin and (2) the virtual disappearance after hypophysectomy of the diabetes induced by depancreatization. Animals with both pancreas and hypophysis removed are found to live longer than ordinary depancreatized animals, apparently because of the relatively normal level of dextrose in the blood, complete absence of ketosis, more normal respiratory quotients and reduction of excessive consumption of nitrogen stores.²

Hypoglycemic episodes occur often in diabetic hypophysectomized animals, especially during fasting, and such animals may die in an attack of hypoglycemic crisis. If sugar is given, recovery is usually spectacular but the hypoglycemic crisis recurs unless feeding is maintained. Hypoglycemia in these animals can be prevented if injections of anterior pituitary extracts are given. Hypoglycemic crises may occur as well in nondiabetic hypophysectomized animals, but only when they are kept in a fasting state. Well fed nondiabetic hypophysectomized animals, on the other hand, usually have normal blood sugar levels and carbohydrate reserves.

From these facts it is obvious that the pituitary has a regulatory effect on the blood sugar and is concerned with its maintenance during fasting. At present, two theories are advanced to explain this action: (1) the anterior lobe regulates the available dextrose by stimulating its formation from endogenous protein and possibly from fat, and (2) the anterior lobe regulates carbohydrate oxidation by some stimulating-inhibiting effect.

From the University of Cincinnati College of Medicine and the Cincinnati General Hospital.

In considering the material just presented it should be mentioned that more recently Long and Lukens³ have produced effects very similar to those obtained by hypophysectomy by complete removal of the adrenal glands in diabetic animals. They consider that hypophysectomy alleviates diabetes by provoking adrenal hypofunction.

While these effects have often been described in a variety of experimental animals, they have rarely been observed in man. Decreased tolerance for sugar has been noted in Cushing's syndrome and in acromegaly associated with hyperplasias of the pituitary body. On the other hand, increased tolerance to dextrose is seen in the destructive or atrophic lesions of the pituitary body, classified clinically as Simmonds' disease.⁴ Here the destruction of glandular tissue causes an apparent diminution in the diabetogenic hormone due to what Simmonds considered embolic occlusion of the end arteries of the anterior lobe or to what others have shown to be thrombosis, tuberculosis, metastatic cancer, gumma or abscess. If the destruction occurs suddenly and massively, death may occur before the typical symptoms of Simmonds' disease can occur. Such patients have low blood sugar levels, similar to the low blood sugar level in the hypoglycemic crisis of an experimental animal, and exhibit a general slowing of most physiologic activities. Many case reports, substantiated by postmortem observations, can be found in the literature, some presenting a picture of acute necrosis of the gland similar to that reported here. These are summarized in reports by Calder⁵ and by Silver.⁶

Reports of cases in man duplicating Houssay's phenomenon are definitely rare. Lyall and Innes⁷ in 1935 reported a case of severe diabetes mellitus which was ameliorated by a lesion of the pituitary body and which finally became sensitive to insulin but showed no spontaneous hypoglycemia. Some authors⁸ have attempted roentgen therapy to the hypophysis in diabetes mellitus. Chabanier and his associates⁹ reported a case of severe diabetes in which they did an ablation of the anterior lobe of the pituitary body in an effort to effect a cure. Prior to operation the blood sugar averaged 400 mg. per hundred cubic centimeters and the patient took from 150 to 170 units of insulin a day with a carbohydrate intake of only 80 Gm. a day. After removal of the pituitary body the blood sugar ranged between 75 and 220 mg. per hundred cubic centimeters and the diabetes generally improved. However, the patient's quiescent pulmonary tuberculosis became reactivated, after which the dextrose tolerance again decreased and death occurred five months after the operation.

The following case illustrates some of the phenomena described in experimental animals and may be regarded as an example in the clinic of the "Houssay animal":

REPORT OF CASE

History.—A white man aged 40, unmarried, was admitted to the Cincinnati General Hospital at 6 p. m. Oct. 10, 1938, in a semistuporous condition. The history was difficult to obtain but was supplemented by information from his relatives.

The patient was reticent and unsocial. He lived alone and had few friends and intimates. When in Ireland, five years before admission to the hospital, a diagnosis of diabetes mellitus was made. He followed no rigid, planned diet thereafter but eliminated certain foods on a qualitative and quantitative basis. He was known to test his urine regularly and took insulin more as the need arose than on a definite schedule.

About two months before admission he complained of loss of weight and of weakness, and a short time later of pain in the left side of the chest accompanied by a chronic cough with expectoration, night sweats and easy fatigability. He refused to stop work despite increase in severity of his symptoms.

Two weeks prior to admission he noted a generalized headache, which after a week became so severe that he was taken to his uncle's home. During the two days spent there he was excessively weak and lethargic and coughed frequently; swelling of the ankles was noted. However, at the end of this time he insisted on walking about three miles back to his room and returned to work. Three days before admission he was forced again to go to his uncle's home, where he remained in bed con-

Fig. 1.—In this sagittal section through the pituitary body, A represents approximately normal glandular tissue and B represents an infarct of the anterior lobe with extensive areas of necrosis. Hematoxylin-eosin stain. Reduced from a photomicrograph with a magnification of 15 diameters.

stantly. At this time he tested his urine and it was noted that the blue solution changed to a yellowish color. Extreme weakness, sweating and restlessness were outstanding symptoms. His appetite was only fair, and he ate only a few eggs, bread and lamp chops during the three days preceding admission; during this time, however, it is definitely known that he took no insulin. Dr. J. P. Beneke saw him on the day before admission and found that his urine contained an excessive amount of sugar. On the morning of the day of admission he appeared much worse than on the preceding day. There were pallor, sweating, urinary incontinence and such excessive weakness that he could not talk above a whisper. Because of his precarious condition he was referred to the Cincinnati General Hospital.

Physical Examination.—The patient was emaciated. He was semistuporous, perspired freely and lay quietly in bed without much complaint. The temperature was 102.8 F., pulse rate 98, respiratory rate 25 and blood pressure 108 systolic, 50 diastolic. Over the legs there were a few reddish macular areas of irregular outline about 1 cm. in diameter, not fading on pressure. The pupils were equal and reacted to light. Ophthalmoscopic examination revealed no abnormalities.

The trachea was in the midline. The thorax was of the long, thin type, with moderate pigeon breast deformity of the upper part of the sternum. Respirations were feeble, shallow and equal. Resonance was impaired over both apices, with dullness in the left interscapular area. Many rhonchi were heard bilaterally. There were constant fine rales over the upper lobe of the

left lung posteriorly and also over the base of the right lung. The breath sounds were somewhat increased over the entire left side of the chest. The heart was not enlarged. Its rhythm was regular and there were no murmurs. All pulses were equal but of poor volume. The abdomen was level with the chest, was lax, and moved freely with respirations. No masses or tenderness was found. The liver, spleen and kidneys were not palpable. The rectal examination disclosed a normal con-

Fig. 2.—In this higher magnification *A* represents the margin of the infarct and *B* the necrotic portion of the infarct. Hematoxylin-eosin stain. Reduced from a photomicrograph with a magnification of 100 diameters.

dition. A small amount of edema of the ankles could be demonstrated. There was no cyanosis of the extremities or clubbing of the fingers. The neurologic examination showed normal status as far as the patient's cooperation permitted testing.

Laboratory Data.—Examination of the blood revealed the following values: hemoglobin 11.3 Gm., red cell count 3,330,000, white cell count 8,800 with 84 per cent neutrophils, 1 per cent eosinophils, 1 per cent basophils and 14 per cent lymphocytes. The platelets were normal in amount. A specimen of urine obtained by catheterization presented a specific gravity of 1.018 and contained no albumin, sugar, acetone or abnormal microscopic elements. The stool was normal. The sputum was purulent and contained moderate numbers of tubercle bacilli. The Kahn reaction in the blood was negative. Tests of blood sugar and carbon dioxide combining power were made on admission but not reported as emergency procedures because of a normal picture on urinalysis. A spinal tap showed normal pressure and normal cytologic and serologic features. The cerebrospinal fluid protein was 12 mg. and the chlorides 636 mg. per hundred cubic centimeters.

Course.—The patient remained in a semistuporous state during his eighteen hours in the ward. The temperature rose to 104 F., the pulse rate fell sharply to 75 and later to 60 and the respiratory rate remained between 20 and 30. Terminally, cyanosis of the extremities became apparent, and death took place without any other appreciable change.

Reports on the blood chemistry were returned a few hours after death. The blood sugar level was 31 mg. per hundred cubic centimeters on admission and the carbon dioxide combining power 58 volumes per cent. The uric nitrogen was 19 mg. per hundred cubic centimeters. Twelve hours later the blood sugar was less than 20 mg., a figure too low to be accurately read by Folin's method. The spinal fluid sugar similarly was less than 20 mg.

The patient was thought to have far advanced pulmonary tuberculosis, tuberculous pneumonia and hypoglycemia of undetermined origin.

Postmortem Observations.—An autopsy was performed by Dr. Sabro Tashiro eight hours after death. The body was well developed and poorly nourished. There was clear straw-

colored fluid in the right and left thoracic cavities. There were numerous nodular areas presenting caseation and cavitation throughout both lower lobes and the left upper lobe of the lungs. Examination of the gastrointestinal tract revealed acute ileitis with focal fibrino-purulent peritonitis. On microscopic examination the lungs presented a picture of miliary tuberculosis. There was also microscopic evidence of toxic myocardiosis and chronic passive congestion of the liver. On microscopic examination of tissue from the kidneys, in addition to toxic nephrosis, vacuolation of the cells of the loops of Henle was noted, a change encountered in cases of diabetes mellitus. Gross and microscopic examination of the pancreas and both adrenal glands (fig. 3) revealed no abnormalities. The pituitary gland presented no gross abnormalities. On microscopic examination of the pituitary gland there was noted an area of partially disintegrated, very pale staining cells implicating the entire anterior lobe except for a few normal glandular cells along some portions of the periphery (figs. 1 and 2). In the border of the ischemic area the capillaries were filled with blood and there was some extravasation of blood. In scattered areas throughout the ischemic area, nuclear fragments were found. The pars intermedia and pars nervosa were not affected, although the blood vessels in these portions of the gland revealed a moderate degree of congestion. A diagnosis of massive infarction with necrosis of glandular tissue of the anterior lobe of the pituitary gland was made.

Gross examination of the brain after fixation in solution of formaldehyde revealed cerebral congestion and moderate cerebral edema. Microscopic examinations of serial sections through the diencephalon revealed an excessive amount of glial proliferation throughout the hypothalamus but especially intense in the paraventricular nucleus and nucleus supra-opticus. Both of these nuclei presented very advanced retrograde changes in the neuron cell bodies with frequent evidence of shadow cells and cell death. There was intense vascular congestion throughout the anterior hypothalamus with some areas of extravasated blood in the subependymal area in the region of the hypothalamic sulcus. There was a pronounced subependymal gliosis.

COMMENT

This diabetic patient was, in effect hypophysectomized and he died in acute hypoglycemia. Lacking other objective knowledge, we have the following evidence that he was diabetic: (1) A diagnosis of diabetes

Fig. 3.—The normal adrenal gland. Hematoxylin-eosin stain. Reduced from a photomicrograph with a magnification of 100 diameters.

mellitus was made in an Irish hospital and was followed by regular urinalysis for sugar, (2) marked glycosuria was noted by his physician as late as thirty-two hours before admission, (3) used and unused insulin and syringes were found among his belongings after death, and (4) glycogenic degeneration of the loops of Henle was found on microscopic examination of tissue from the kidneys.

The necrotic process involving the anterior lobe of the pituitary gland has been demonstrated. The pathologic picture suggests a very recent occurrence because of a lack of organization and because of the very slight amount of cellular reaction. The cause of the infarction remains a matter of speculation. The history indicates that a necessary factor for hypoglycemia, namely fasting, was present. The poor intake of food preceding death, plus the added burden of infection, probably lowered the glycogen stores to a pronounced degree. At the time of death the patient's blood probably contained no sugar, since levels around 20 mg. per hundred cubic centimeters are thought to be due to other reducing substances in the cells, especially glutathione. It is interesting to note that the patient showed no convulsive phenomena associated with the extreme hypoglycemia.

SUMMARY

A patient with diabetes mellitus of five years' duration had severe terminal hypoglycemia. Autopsy revealed an infarct of the pituitary body with destruction of the anterior lobe. The case was complicated by acute ileitis, localized purulent peritonitis and pulmonary tuberculosis. The evidence presented appears to justify the conclusion that the case represents one of the few recorded examples of the Houssay phenomenon in man.

Clinical Notes, Suggestions and New Instruments

THE NATURE OF THE RENAL LESION WITH SULFAPYRIDINE THERAPY

WALTER A. STRYKER, CHICAGO

Although the gross presence of urinary calculi as a consequence of sulfapyridine therapy has been reported both experimentally and clinically,¹ no calculi have been seen in microscopic preparations. The most constant finding in the microscopic examination of the kidneys in the reported postmortem examinations has been marked dilatation of both convoluted and collecting tubules and of the glomerular spaces. The cause and nature of these lesions have not been demonstrated, how-

ever. The calculi and the associated disturbances in renal function constitute the most disturbing complication of the use of sulfapyridine and, as stressed by Bensley,² measures designed to prevent such a complication cannot be adequately determined until more is known of its cause. In the case reported here calculi, present grossly, were likewise demonstrable in the histologic preparations of the kidneys, and the etiology of the described cortical lesions could be determined.

REPORT OF CASE

A child aged 5 months was admitted to the Illinois Central Hospital, in the service of Dr. Everett Laury, Oct. 19, 1939, with symptoms of meningitis. Spinal fluid on examination revealed pneumococcus type VIII, and on the day after admission sulfapyridine therapy was initiated in addition to the use of polyvalent antiserum. The first three days 52½ grains (3.4 Gm.) of the drug was given. During the four weeks the child was in the hospital a total of 44.2 Gm. of sulfapyridine was administered. Ten days after the initial dose gross hematuria appeared and was constantly present thereafter. Sulfanilamide

Fig. 1.—Section of cortex of kidney, showing numerous calculi in tubules (indicated by arrows) and dilatation of tubules and glomerular spaces. Slightly reduced from a photomicrograph with a magnification of 110 diameters.

was given for two days with a total dosage of 28 grains (1.8 Gm.). On November 11, examination revealed 8.7 mg. of sulfapyridine per hundred cubic centimeters of blood. Urine studies were not made during the last few days of life because of the difficulty in getting sufficient urine for analysis. The patient died on November 16.

At autopsy the diagnosis of persisting pneumococcal meningitis was confirmed. The kidneys were greatly enlarged, weighing 85 Gm. each, as compared with a normal average weight of 25 Gm. for the age of the patient. The cut edges bulged markedly. In the calices and pelves of both kidneys there was a small amount of yellow-white gravel; from the pelvis of the right kidney four calculi measuring up to 1.5 mm. in diameter were isolated. Neither the pelvis nor the ureter was dilated. In both ureters and in the urinary bladder there was gravel similar to that in the kidneys; this was most prominent at the entrance of the ureters into the bladder. The mucosa of the urinary tract appeared normal.

Sections of the kidneys were prepared by a "rapid" celloidin technic as well as by the usual slower celloidin method. The sections prepared by the former method showed numerous basophilic crystals and other structures in the tubules of the kidney, as described later. In most of the sections prepared by the usual celloidin method, however, no such material was visible, and the appearance was essentially that described in previous reports. The chief difference in the two methods was in the length of time the tissue was in contact with water or dilute solutions, either in the washing of the tissues or in the concentrations of the stains. In an attempt to determine whether the loss of the material in sections might be due to its solution by water, sections of a portion of tissue which exhibited numerous calculi by the rapid relatively anhydrous technic, when examined after contact with water for twenty-four hours, showed a marked quantitative reduction in the amount of the precipitated material in the tubules. In view of these results it appears possible that earlier failure to demonstrate calculi might have been due to the use of techniques which dissolved the material. Experimental work to determine the relation of the calculi to the solvent is in progress.

In all the sections there was a marked dilatation of both convoluted and collecting tubules in the cortex, with only occasional dilatation of the tubules in the pyramids. There was also dilatation of Bowman's spaces, with compression of glomerular tufts. These dilatations indicated that the collecting tubules were obstructed. The dilated tubules contained large amounts of basophilic and eosinophilic material present in the form of single or aggregated spherules. The amount of distention of the tubules, as well as the method of preparation of the sections, did not permit accurate identification of each tubule, but the material appeared to be present in both the convoluted and the collecting types. In the medullary rays many of the loops of Henle and the smaller collecting tubules were completely

Fig. 2.—Section of pyramid of kidney, with plugging of loops of Henle and small collecting tubules by basophilic material. Slightly reduced from a photomicrograph with a magnification of 430 diameters.

plugged by the foreign material. This material, both here and in the cortex, was of varying structure. There were many sharp edged basophilic crystals, amorphous basophilic debris and numerous discoid bodies composed of homogeneous material chiefly eosinophilic but occasionally appearing to be a mixture of eosinophilic and basophilic matter. In the washed sections the location of these discoid structures was indicated by eosinophilic bodies of similar form having the appearance of skeletons of

the homogeneous masses from which some of the material had been dissolved. These were presumably the protein stroma of the minute globules. In sections prepared from a large block by the usual technic the kidney pelvis contained basophilic masses with rarefied centers. The walls of these masses were bordered by radiating basophilic needles.

Chemical analyses of the concretions in other cases have revealed that they consist chiefly of acetylsulfapyridine and free sulfapyridine. Marshall³ has explained the formation of the

Fig. 3.—Section of calyx of the kidney, with basophilic mass. The center is rarefied; the walls are formed by radiating basophilic needles. From a section prepared by the usual technic. Reduced from a photomicrograph with a magnification of 360 diameters.

crystals as a probable precipitation in the tubules of the kidney as the urine becomes more concentrated. This theory would seem to be supported by the observations made in this case. The material is apparently precipitated in the proximal portions of the tubules, collects in the loops of Henle and the smaller collecting tubules and causes plugging of these excretory ducts. The result of this is the marked dilatation of the tubules and glomerular spaces previously described in other reports. This appearance is in contrast to the more common formation of calculi at the tips of collecting tubules, which causes marked dilatation of the tubules in the medulla and less distention of the cortical elements. It has been suggested² that the extent of serious or permanent interference with renal function would depend on the fact that the precipitation of the acetylsulfapyridine was so extensive as to produce blockage of the tubules. Such a process has been demonstrated here and, although complete blood chemistry studies were not made in this case, marked retention of nitrogen has been shown to occur in other cases presenting hematuria and the formation of urinary crystals after treatment with sulfapyridine. Attempts to prevent this complication apparently must be based on practices designed to prevent the precipitation of the crystals. Two precautions have been used. The solubility of acetylsulfapyridine is reported to be less in acid than in alkaline mediums,³ and hence alkalization of the urine, chiefly by the use of sodium bicarbonate, has been used. The efficacy of this technic is still being determined. Use of large amounts of fluids to prevent concentration of the urine has apparently been successful in several cases, and there is some indication that such a procedure may wash out material previously present. In view of the site of the renal changes, as demonstrated in this case, such a practice would seem to be advisable.

SUMMARY

Precipitation of acetylsulfapyridine in the kidney was found at autopsy of a patient after treatment with sulfapyridine. The marked dilatation of cortical tubules and glomerular spaces characteristic of kidneys in cases of sulfapyridine toxicity seems to depend on intratubular precipitation of the drug or its compounds. There is a possible explanation for the previous difficulty in demonstrating the material in histologic sections.

AURICULAR FIBRILLATION OBSERVED FOR
TWENTY-FIVE YEARSLOUIS FAUGERES BISHOP, M.D., AND LOUIS FAUGERES
BISHOP JR., M.D., NEW YORK

Our primary reason for reporting this case is to illustrate what can occasionally be accomplished in auricular fibrillation.

REPORT OF CASE

History.—A woman aged 55 came to our office on Dec. 17, 1914, complaining chiefly of palpitation and dyspnea on exertion. Her past and family histories were not significant.

At the time of this examination her pulse rate was noted to be 130; the blood pressure was 130 systolic, 105 diastolic. A polygram done at this time indicated that the patient had auricular fibrillation. The auricular fibrillation was studied between the years 1914 and 1939, covering a period of twenty-five years. She was observed at fairly regular intervals.

The auricular fibrillation was first treated in 1914 with an infusion of digitalis. Later in 1916 she began to take doses of powdered leaves varying between 2 and 3 grains (0.13 to 0.2 Gm.) daily and continued it for the remainder of her life, which was for twenty-three years. An estimate of the amount of digitalis consumed between 1914 and 1939 would be $3\frac{1}{2}$ pounds.¹

During observation, 1914-1923 inclusive, her activities were normal. Her blood pressure was 150 systolic, 90 diastolic. The ventricular rate was approximately 90. Her digitalis

Fig. 1.—One of forty-three polygrams taken with the Mackenzie polygraph showing absence of the A wave in the jugular pulse and the irregular radial pulse (done in 1914).

dosage was $1\frac{1}{2}$ grains (0.1 Gm.) a day, except for one brief period when she omitted it, when it was necessary for a short time to increase it to 3 grains.

The only signs and symptoms noted were slight swelling of the ankles and numbness of the right arm.

In 1931 mild congestive failure was noted as evidenced by moist rales at the left base, which improved when her digitalis

Fig. 2.—Tracing done May 26, 1919.

dosage was increased. Again in 1932 moist rales were noted at both bases, as well as a slightly tender liver. Digitalis dosage was now 2 grains a day. Her blood pressure had risen to 180 systolic and 80 diastolic. During February and March 1934 marked congestive failure gradually developed, and in March 1934 dehydration therapy was begun, which was continued up to the time of her death in September 1939.

In addition to the continuous use of digitalis, ammonium chloride was employed. Over this period she received several types of mercurial diuretics, including the salyrgan types; the

salyrgan was given for the most part intramuscularly and the mercuripurin intravenously. Mercurial diuretics were administered a total number of forty-six times in doses of from 1 to 3 cc.

Abdominal ascites became a great problem toward the end of her life, and in addition to mercurial diuretics it was necessary to do six abdominal paracenteses.

The woman's death occurred rather suddenly in September, four days after her last paracentesis and her last mercuripurin injection. She had a chill and elevation of temperature and went rapidly into coma, dying within approximately twelve hours.

Fig. 3.—Tracing done April 19, 1933.

Pathologic Examination.—Anatomic Diagnosis: 1. Heart. (a) Chronic rheumatic heart disease with mitral stenosis. Calcification of left auricle wall. (b) Concentric atherosclerosis of left coronary artery with stenosis. (c) Left and right ventricle, myocardial hypertrophy. (d) Myocardial dilatation, chiefly right auricle.

2. Liver. Fine diffuse cirrhosis.

3. Spleen. Chronic passive congestion.

4. Aorta. Thrombo-ulcerative atherosclerosis, descending portion.

5. General. Pulmonary edema and atelectasis. Hydrothorax and ascites, edema.

Cause of death. Myocardial insufficiency. Etiology: mitral stenosis, left coronary artery stenosis, and hypertrophy and dilatation of myocardium.

SUMMARY

1. In watching a case of this type over a period of twenty-five years one is impressed with the fact that the prognosis lies to some extent in the cooperation of the individual with the disease.

2. In observing an example of mitral stenosis such as this one, certain conclusions become evident. Although there is no definite evidence of when the mitral lesion developed first, it can be inferred that there was no progressive lesion. The mitral stenosis offered little embarrassment to the heart, and this woman reached extreme old age without heart failure. In addition to the mitral lesion, it was noted post mortem that there was evidence of coronary artery disease as well.

3. The mercurial diuretics which she received for the last five years were undoubtedly an important factor in prolonging her life at the end. Although the case itself is a fine example of the prolongation of life by the continuous use of small doses of digitalis, the mercurial diuretics certainly take precedence over digitalis in congestive failure when edema is a prominent feature. In spite of the use of mercurials over this period there were no changes noted in the kidneys which could be attributed to mercury.

The results with few exceptions were remarkable, since the patient always lost from 8 to 10 pounds (3.6 to 4.5 Kg.) of edema following every injection.

ADDICTION TO AMPHETAMINE SULFATE

SIDNEY FRIEDENBERG, M.D., CAMDEN, N. J.

While the more spectacular effects of the new drug amphetamine sulfate (benzedrine sulfate) have been given prominence by recent reports, from my own observation its most popular use, that in the treatment of obesity, has been attended by a paucity of reports and with an evident disregard for the habit-forming qualities of amphetamine.¹

Lesses and Myerson,² postulating an altered appetite regulation in many of the obese, were able to place their patients, by the psychically stimulating and appetite-reducing effects of amphetamine, on a low caloric diet, to which they adhered. Amphetamine has been used successfully by Rosenberg³ to decrease the appetites of a large series of obese patients in conjunction with a low caloric diet. Christian⁴ condemns its use in the treatment of obesity.

My purpose in this report is to warn against the possibility of addiction by the continued use of this new stimulating drug in the routine treatment of obesity.

REPORT OF CASE

A woman aged 30 was 5 feet 1 inch (155 cm.) in height and weighed 190 pounds (86 Kg.) in March 1939. She expressed a desire to lose some of her "all too investing" flesh. Previous to 1931 her weight had been 135 pounds (61 Kg.); following a hysterectomy and a bilateral oophorectomy in that year her weight rose to 190 pounds, remaining there with a few sporadic intermissions, during which she had taken thyroid substance as high as 5 grains (0.3 Gm.) daily with immediate loss of weight, subsequent toxic effects and a relapse. She had occasional menopausal symptoms. Examination revealed a moist skin and proptotic eyeballs—later found to be a hereditary characteristic—which had no difficulty in converging. There was no lid lag and the forehead wrinkled easily. A coarse finger tremor was present. The pulse on many occasions was 92. The temperature was always within the normal range. The blood pressure was 120 systolic, 86 diastolic. The thyroid gland was not palpable. The basal metabolic rate was —11. There were no other significant manifestations. The fasting blood sugar was 98 mg. per hundred cubic centimeters. The Wassermann reaction of the blood was negative. Urinalysis and a complete blood count were within normal limits.

During the course of several weeks on a low caloric diet she lost no weight. In May 1939 she was given 5 mg. (one-twelfth grain) of amphetamine sulfate morning and afternoon with the same diet. During the next few months her weight slowly decreased, the amphetamine being increased gradually to 10 mg. (one-sixth grain) twice a day. The blood pressure remained stationary.

In October 1939 it was decided to decrease the dosage of amphetamine to 5 mg. twice a day with the object of eventually stopping the drug altogether. After a week on this dosage she complained that she felt worn out and depressed—a new complaint for her. The next week she was placed on a placebo and returned in seven days urgently demanding that she be placed on a higher dosage. She now feels that she cannot do without her pills and cannot carry on her arduous occupation (beautician) without the stimulus that the amphetamine supplies. Since she is the family bread winner, the problem is not a minor one.

COMMENT

The continued use of amphetamine may result in addiction. Possible deleterious results from long continued use have not yet been investigated fully.

Special Articles

THE PHARMACOPEIA AND THE PHYSICIAN

PEDIATRIC EMERGENCIES

JOSEPH BRENNEMANN, M.D.

CHICAGO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.

Pediatric emergencies find themselves in strange company in a series of papers devoted to "extending information to physicians on the use of official medicines," since relatively few of them require medicinal treatment. When they do, however, the indications are nearly always simple, single and mandatory, and the results are favorable. Only such emergencies will be discussed as occur, alone or predominantly, in childhood or that differ significantly from those of later life.

NEWBORN PERIOD

The newborn infant presents emergencies that are unique. Asphyxia of any degree calls for respiratory stimulation. In the mildest cases flicking cold water or ether on the chest is often all that is necessary. In all the more serious cases the methods of choice, and the most effective, are the use of carbon dioxide inhalation and the Drinker respirator. Yandell Henderson¹ gives the following directions: "The carbon dioxide required for the initial resuscitation should be of whatever strength is needed to induce respiration, but after respiration is started 7 per cent or even 5 per cent is generally sufficient. . . . In premature or otherwise weak babies . . . the inhalation of 5 or 6 per cent carbon dioxide should be repeated several times during the first few days." If these resources are not available some gentle form of artificial respiration must be employed.

Intracranial hemorrhage due to injury at birth, even if it is of clinical significance, offers serious difficulties both as to diagnosis and as to its relationship to asphyxia in a given case. If there has been a difficult and prolonged or a precipitous labor, if the anterior fontanel is tense and full, if there are convulsive seizures, especially if unilateral together with coma, one may assume that this is due to a hemorrhage. If such conditions are not present it is commonly impossible at this time to differentiate a birth injury from a developmental anomaly of the brain. Lumbar puncture probably does no good and from the very nature of the procedure may do harm by increasing intracranial pressure at the time and so inducing more bleeding. If the fontanel is very tense and coma persists, the intravenous injection of from 20 to 50 cc. of 20 per cent dextrose may be of value. Since rest, as nearly absolute as possible, with the use of sedatives if necessary, is the one imperative indication, it is obvious that no disturbing procedure should be employed unless it is clearly indi-

1. Henderson, Yandell: Respiratory Stimulants and Their Doses, J. A. M. A. 108: 471-475 (Feb. 6) 1937.

cated. Gavage is necessary after a time if food is not taken naturally.

Hemorrhagic disease of the newborn is one of the dramatic emergencies of this period. About the third day of life the baby begins to bleed from multiple sources—mouth, nose, bowels, vagina, subcutaneous tissues, body cavities, internal organs and even into the brain. Bleeding from the bowel and a slight oozing from the vagina, when this occurs alone, has a different cause and is of little significance. Injection of 20 cc. of human blood, usually from the father, 10 cc. in each buttock followed on the next day by an equal or greater amount of blood serum if the bleeding has not been arrested, has reduced a former mortality of nearly 100 per cent to one that approaches zero. The disease is apparently on the wane and may have something to do with the mother's diet.

Tetany, or hypocalcemia, of the newborn has attracted increasing attention in recent years. The symptoms are much like those of tetany of a later period, with convulsions as the outstanding and most alarming symptom. Chvostek's sign is usually positive but often occurs in the normal newborn infant. The blood calcium is far below the normal 9 to 10 mg. per hundred cubic centimeters of blood. If there is no other obvious cause for the convulsions, treatment should be begun at once without waiting for a calcium determination. In milder cases calcium chloride or calcium gluconate may be given by mouth. In more serious cases 10 cc. of a 10 per cent solution of calcium gluconate should be given intravenously or intramuscularly. To this may be added 20 units of solution of parathyroid subcutaneously. Calcium chloride by mouth may be continued for a time, if necessary, until a sufficient amount of calcium has been obtained from milk in the infant's food.

Congenital atresia of the esophagus is not an extremely rare condition. In nearly all reported cases the upper dilated portion of the esophagus ends blindly at about the bifurcation of the trachea, and the lower attenuated portion passes directly from the stomach into the trachea at or near the bifurcation or into a bronchus. The stomach is usually distended, the lower part of the abdomen retracted. Saliva runs from the dependent corner of the mouth and after taking more than two swallows of water the infant chokes, water gushes from his mouth and nose, he becomes profoundly cyanotic and death seems imminent. The diagnosis may be confirmed by x-ray examination after a small amount of barium sulfate is given by mouth or by finding that a catheter passed into the esophagus ends at about 12 cm. from the alveolar border of the mouth. Gastrostomy, with and without preliminary tying off of the gastric end of the esophagus, and jejunostomy have been tried. No child has ever lived, and with the consent of the parents one is justified in letting the child die without treatment. Death follows around the end of the first week of life from bronchopneumonia and starvation.

GASTROINTESTINAL TRACT

Appendicitis presents a true emergency in the first day or two or even three. If uncomplicated, the fever is usually low, the pain not intense, the white blood count moderately high, and vomiting nearly always occurs early. Point tenderness, more marked and more significant than unelicited pain, occurring most often at or below McBurney's point but also anywhere from the flank to the pelvis and, rarely, even to the left of the left rectus muscle, is the single most important sign in

the early stages. In this early period there is usually a voluntary protective contraction of the muscles; involuntary boardlike rigidity indicates peritoneal involvement. Operation is usually clearly indicated in the first two or even three days and at any time if there is spreading peritonitis. If the patient is seen on the third or fourth day and there is an evident tendency for the inflammatory process to become walled off, it is safer to await the disappearance of the mass and to operate a month or two later. In an instance of acute so-called primary peritonitis, nonappendical in origin and due to a pneumococcus or a streptococcus, it is usually better not to operate until localization has taken place. Sulfanilamide or sulfapyridine is indicated depending on whether the cause is a hemolytic streptococcus or a pneumococcus.

Acute intestinal obstructions are relatively frequent in childhood. In the newborn there may be congenital absence or narrowing of a portion of the intestine, more often in the distal ileum, leading to great distress, distention of the abdomen, uncontrollable biliary vomiting and absence of meconium and feces. Surgery is indicated but offers little as a rule. The commonest type of intestinal obstruction is intussusception, usually at the ileocecal junction and predominantly in the first year of life. The onset is uniquely sudden, so that the exact hour of its occurrence is nearly always stated. The child begins abruptly to scream with intense, intermittent, colicky pain, soon followed by vomiting and a varying degree of shock. After a time the pain becomes less severe; he no longer screams or even cries, but with each return of the pain he winces or sighs, draws up his legs or turns over in bed. He no longer smiles, and there is a distant, abstracted, serious, resigned, apprehensive expression that may be misleading but is actually of diagnostic value. Cardinal signs in addition to those mentioned are a slightly tender, sausage-shaped mass, usually in the transverse or descending colon, occasionally in the rectum or even appearing externally, and blood in the stools, though not always in the first one. After this there may be some feces, but there is characteristically an intimate mixture of blood and mucus—rarely only thick, white, glairy mucus. The blood is never copious and never clots, unless there is also a bleeding Meckel's diverticulum (to be discussed later). Of practically pathognomonic significance is a silent spurt of a small amount of a turbid currant jelly-like mixture of blood and mucus which follows the retreating finger after a digital examination. An early intussusception may occasionally be reduced by injecting air or barium sulfate and making gentle pressure under the fluoroscope. Valuable time, however, should not be lost before resorting to surgery, as the condition is a real emergency. Similar obstructions with like indications for treatment occur with volvulus, bands, post-operative adhesions and Meckel's diverticulum. There is usually no definite mass, and there is no blood in the stools; however, both these conditions may occur if Meckel's diverticulum is the starting point of an intussusception.

A hernia, commonly inguinal, may become incarcerated or strangulated. An incarcerated hernia can often be reduced in infants and young children by suspending the body by the feet so that the hips are elevated some distance above the bed. If reduction does not take place after a reasonable time, operation is indicated. Strangulated hernia usually presents more serious symptoms and more urgent indications for treatment. There is

persistent vomiting, pain, tenderness and often shock. Reduction is no longer possible without operation.

Hemorrhage from the bowels is always an arresting symptom and a potential emergency condition. While slight hemorrhages, commonly of obvious causation, occur with papilloma, foreign body, dysentery, intussusception, scurvy, Henoch's purpura and blood dyscrasias, and larger ones with gastric or duodenal ulcers characterized by tarry stools, a copious bright red hemorrhage should always lead one to suspect a bleeding Meckel's diverticulum. The diagnosis is almost certain if the blood clots and is at times bright red and at others darker in color. The bleeding is due to ulceration of so-called misplaced gastric mucosa in the wall of the diverticulum. Rarely, but ominously, the extent of the hemorrhage may not be obvious if only part of the blood is passed. Sudden pallor and marked evidence of secondary anemia should lead to investigation. The hemorrhage commonly ceases spontaneously, but if it persists it is fairly free, and if the diagnosis seems justified the diverticulum should be removed. Perforation of the ulcer, with or without hemorrhage and simulating appendicitis, may occur and even more clearly calls for surgical intervention. Recent observations have shown that a like clinical picture can be produced by papillomas in the colon (demonstrable by x-ray examination).

Foreign bodies in the pharynx may present alarming symptoms, and removal may require skilled assistance. The usual attempt to remove the body with the finger should be avoided except in extreme emergency. If lodged in the esophagus, usually in the upper part, the symptoms may be restricted to discomfort and difficulty in swallowing. Early removal is imperative for fear of rupture into the mediastinum and the pleural cavity, which carries a very high mortality. As a rule, a foreign body that has passed into the stomach will escape through the pylorus and cause no harm in the intestinal tract. Long or peculiarly shaped bodies such as a hairpin or a "bobby pin" may not be able to pass the windings of the duodenum and should be removed from the stomach by an endoscopist, if available; if not, by a surgeon. The x-ray examination is of great value throughout if the foreign body is radiopaque.

RESPIRATORY TRACT

Foreign bodies in the respiratory tract are a common cause of emergency in childhood. In the larynx they may lead to alarming obstruction to breathing. There is usually an inspiratory stridor, hoarseness and a croupy cough that may simulate membranous croup. A pedunculated papilloma of the larynx caught between the vocal cords may produce the same symptoms. There is, however, usually a history of preceding stridor and hoarseness of long standing. In the trachea, if the foreign body is large enough, both main bronchi may be obstructed, resulting in death. If there is only partial obstruction of the trachea or of one main bronchus, there will be an expiratory wheeze that may easily be mistaken for asthma. If the partial obstruction of the bronchus is of the right degree there will be, in addition to the wheeze, an obstructive emphysema on the affected side with possibly eventual respiratory silence and both exaggerated breathing on and displacement of the heart to the opposite side. If the bronchial obstruction is complete, the characteristic signs on the affected side are dulness, absence of breath sounds or bronchial breathing and bronchophony, with exaggerated

breathing on the opposite and displacement of the heart toward the affected side. A roentgenogram is obviously of great confirmatory help in diagnosis whether the body is radiopaque or not. Bronchoscopic removal of the foreign body is indicated at the earliest possible time; imperatively so if it is of vegetable origin, because of the well known serious irritation produced by such substances. Three things may well be stressed: the suspiciousness of a wheeze, the fact that a large percentage of foreign bodies are peanuts, and the fact that, while a foreign body in the respiratory tract is always ushered in by sudden choking, commonly with cyanosis and coughing, the latter is no longer present if the body becomes fixed.

Empyema is a condition calling for immediate action only when there is profound impairment of vital capacity and great displacement of the heart and large vessels. Repeated aspiration or closed drainage with gradual removal of pus is then indicated. A tension pneumothorax, nearly always a pyopneumothorax following rupture of an empyema into a bronchus, with a valvelike mechanism permitting freer entrance than exit of air, commonly presents an urgent condition. There is a tympanitic percussion note, sometimes hard to elicit, shifting dulness and absence of breath sounds on the affected side together with exaggerated breath sounds on and displacement of the heart toward the opposite side. A succussion sound, if present, is pathognomonic. Aspiration is futile. Drainage is indicated usually by the closed gradual method, though replacing tension by a simple pneumothorax through open operation would seem a safe procedure if the air is not allowed to escape too freely for a time.

The croup family, all characterized by laryngeal obstruction, requires careful differentiation, since some of the members are urgently alarming and others only apparently so. Excluding those caused by congenital anomalies, foreign bodies and papillomas, they are all due to inflammation and in varying degree to spasm of the larynx. Spasmodic croup usually is easily recognized, especially if there have been previous attacks and if there is a familial tendency. A young child beyond the period of infancy who has seemed well during the daytime, or has at most a slight respiratory infection, after going to bed at night quite suddenly wakes up with a croupy, barking, brassy, sepulchral cough that is soon followed by loud stridulous breathing, profound respiratory obstruction and great restlessness. The condition seems truly alarming to the uninitiated but is usually quite readily relieved in a warm room by inhalation of steam from a croup kettle or some similar device. The ancient remedy of a teaspoonful of syrup of ipecac is effective but messy and distressing. There may be another attack the following night, but usually there is not.

Catarrhal laryngitis is a simple inflammation of the larynx as part of an infection of the respiratory tract and is characterized by hoarseness, croupy painful cough, inspiratory stridor and fever. Spasm is absent or minimal. The onset is not explosively sudden nor restricted as to time, and the symptoms persist for from several to many days without interruption. The condition is rarely serious and can be ameliorated by having the child kept in a warm room more or less saturated with moisture from a croup kettle or a pan of boiling water. It must be differentiated from membranous croup or laryngeal diphtheria, often not an easy matter at the onset.

Membranous croup is usually less febrile and more insidious in onset but more constantly and definitely progressive. The cough is usually more brassy and tight and the stridor more sharp than in simple laryngitis. As the disease progresses there is profound dyspnea, a loud rasping stridor, retraction of the suprasternal notch and the lower end of the sternum, deep cyanosis and great restlessness. The initial hoarseness descends to a whisper and finally to a complete loss of voice such as rarely occurs with a simple catarrhal laryngitis. As the end approaches, the cyanosis gives way to an ashen gray color and the child ceases to struggle. If there is a membrane in the throat or competent laryngeal observation is available, the diagnosis can usually be made early. A culture of material taken from the larynx may reveal the true nature of the disease but is not dependable, and the result should never be awaited before treatment is begun in a suggestive case. From 20,000 to 40,000 units of antitoxin should be given at once and the result from the culture used as a guide to further treatment. If the dyspnea becomes alarming, as shown by great restlessness, increasing cyanosis and retraction, treatment by suction, intubation or tracheotomy is urgently indicated. Environmental factors will necessarily determine the method of choice in a given case.

Laryngotracheitis, if it can be distinguished except by the course from the more serious condition about to be discussed, usually can be relieved by palliative measures. True laryngotracheobronchitis, involving the bronchi as well as the trachea and larynx, is as serious as membranous croup, if not more so, since there is no specific antitoxin and the course is more prolonged, complicated and exhausting. There is sometimes supraglottic and always laryngeal and subglottic obstructive edema, together with a characteristic involvement of the trachea and bronchi, that leads to the formation of thick, tenacious, gummy, ropy secretions that block the air passages. There are thus in a high degree essentially the symptoms and signs of other forms of croup plus those already described as occurring with foreign bodies in the larynx, trachea and bronchi, together with obstructive subglottic and more rarely supraglottic edema. The indications for treatment are to keep the airways clear. In milder cases bronchoscopic suction and intubation may be successful under favorable conditions. In severer cases presenting marked supraglottic and subglottic edema and bronchial obstruction, tracheotomy is imperative. It alone relieves obstructive supraglottic edema and permits as nothing else does the safe removal of the offending secretions by suction with a catheter or by bronchoscopic aspiration. Retention in a warm room saturated with moisture, not too hot, expert nursing and bronchoscopic and medical teamwork are essential to success in meeting the ominous obstructive conditions that often appear with startling suddenness.

GENITO-URINARY TRACT

Uremia or cerebral edema occurring with nephritis, as manifested by headache, dizziness, somnolence, hypertension and eventually coma and convulsions, calls for prompt relief by intravenous injection of 25 per cent dextrose, 0.5 per cent magnesium sulfate or intramuscular injection of from 2 to 4 cc. of 50 per cent magnesium sulfate at four hour intervals until the blood pressure reaches a safe level. A single, harmless but marked urinary retention of unknown etiology occasionally occurs in childhood. Extreme retention may

occur as a result of painful urination due to ulceration of the meatus from the "ammoniacal diaper." Immediate relief follows a drop of 5 per cent cocaine hydrochloride solution on the ulcer. Repetition is avoided by wet boric acid dressings, or the application of petrolatum and attention to the ammoniacal diaper. The latter is carried out by thoroughly washing, rinsing and boiling all diapers and soaking and drying those which are to be used at night in a saturated solution of boric acid.

Torsion of the testicle, or rather of the cord, is a rare but serious condition. There is sudden, exquisite pain and swelling of the testicle, nausea and vomiting, and often shock. Necrotic gangrene quickly supervenes with relief of subjective symptoms. Immediate operation must be performed if the testicle is to be saved. Campbell² states that removal of the testicle is indicated in 90 per cent of the cases. Spontaneous or therapeutic untwisting of the cord may take place rarely, but even then atrophy is likely to result.

Rupture of a kidney due to a blow or a crushing injury, leading to hematuria and local pain, tenderness and possibly swelling, is nearly always best treated expectantly.

CENTRAL NERVOUS SYSTEM

A convulsion in an infant or a young child occurring at the beginning of a febrile disease or, more rarely, even later in the course of the disease, if the temperature rises rapidly from a low to an adequately high point, has usually the same significance as a chill in an adult and is of relatively little greater importance. It commonly ends spontaneously. If it does not, and especially if there is hyperpyrexia, a tepid, cool or even cold pack is indicated until the fever is reduced to a safe point. Only one thickness or at most two thicknesses of sheet should be used, so that the cooling effect of evaporation may also be called into play. The same procedure will prevent an impending convulsion. Two grains (0.13 Gm.) of acetylsalicylic acid for each year of age, best given in orange or some other heavy syrup, may have the same effect. The use of the conventional hot bath has probably survived only because the convulsion ends in spite of the treatment. If the convulsion still persists it must be controlled even if anesthesia by means of chloroform or avertin with amylene hydrate is necessary. Convulsions occurring periodically during later infancy may be due to tetany and require antirachitic treatment. Occurring periodically at a later period without fever usually means idiopathic epilepsy, although organic disease of the brain must be excluded.

Concussion of the brain, with or without loss of consciousness, is characteristically accompanied by pallor, somnolence and nausea or vomiting. Since organic injury such as hemorrhage has probably taken place, rest is imperative. This is especially indicated if there is a skull fracture, as shown in the roentgenogram, by bleeding from the nose, mouth, ears or into the post-orbital space, or by leakage of spinal fluid. Coma and convulsions or localized twitchings, probably due to hemorrhage, are not infrequent. The present tendency is to avoid spinal puncture for either diagnostic or therapeutic purposes. Rest in bed with restraints for the younger child and elevation of the head of the bed should be enforced for a period of several weeks. The temperature, pulse, respiration and blood pressure

2. Campbell, M. F. The Male Reproductive System, in *Brennemann's Practice of Pediatrics*, Hagerstown, Md., W. T. Prior Company, Inc. 21: 52 (chapter 29) 1956.

should be carefully watched for a time. If coma and hypertension persist, the treatment described for cerebral edema, or even surgical intervention, may be indicated, the latter especially if there are focal signs. Surgery is usually restricted to cases in which there is obvious or well founded suspicion of a depressed fracture. X-ray examination may show a depression restricted to the inner plate of the skull.

METABOLIC DISTURBANCES

Acidosis occurs as a symptom of many conditions, notably in diabetic coma and in alimentary or intestinal intoxications in infancy following great loss of body fluids and overdosage with salicylates or acetylsalicylic acid. The one dependable clinical symptom is hyperpnea or deep breathing, which may early be of normal rate but in more advanced conditions is deep, rapid and pauseless. The urine shows the presence of acetone and diacetic acid, and in diabetic coma there is glycosuria and hyperglycemia. Treatment is urgent. In all cases replacement of body fluids is indicated. In non-diabetic acidosis this should be done by intravenous injection of dextrose and physiologic solution of sodium chloride, or preferably lactate Ringer's solution. In diabetic coma the intravenous administration of Ringer's or lactate Ringer's solution and the intramuscular injection of insulin are urgently indicated. The volume of fluid should be from 20 to 30 cc. per kilogram of body weight and should not be injected faster than 5 cc. a minute. The insulin requirement during acidosis is not less than 1.5 units per kilogram of body weight plus 1 unit for each gram of sugar administered, usually dextrose in 5 per cent solution.

Increasing interest has recently been directed to hypoglycemia. The hypoglycemia of hyperinsulinism is a familiar example. It may, however, occur with startling suddenness and seriousness in other conditions, such as prolonged starvation, inadequate intake of carbohydrate, liver damage and under still other conditions the nature of which requires further observation for clarification. The symptoms vary from irritability, lassitude and somnolence to convulsions and coma. The treatment consists in the prompt administration of orange juice or sugar to restore the blood sugar concentration to normal. If oral administration is impossible or ineffectual, or if the condition is alarming, from 10 to 25 per cent dextrose solution should be given intravenously. The patient is commonly restored to normal while the injection is being given.

Allergy is widespread, and in the markedly hypersensitive individual the injection of a foreign protein such as horse serum may lead to anaphylactic shock and death. Before antitoxin is given the test for sensitivity of the skin should be performed. If positive, the procedure of desensitization should precede the administration of the full dose of serum and the latter should contain an adequate amount of epinephrine. A hypodermic loaded with this drug should be a part of the equipment whenever serum is given.

In acute poisoning the stomach should be washed out thoroughly unless the agent is an escharotic. If the latter is an acid, an alkaline solution should be given; if an alkali, an acid solution, such as diluted vinegar, is given. Information as to antidotes and specific methods of treatment of all other forms of poisoning should be constantly and immediately accessible to every physician.

707 Fullerton Avenue.

MATERNAL MORTALITY, 1938

EDWIN F. DAILY, M.D.

Director, Division of Maternal and Child Health
U. S. Children's Bureau

WASHINGTON, D. C.

The lowest maternal mortality rate ever recorded in the United States, 43.5 per 10,000 live births, has been reported by the United States Bureau of the Census for the year 1938. For the first time on record less than 10,000 (9,953) deaths were assigned to puerperal causes. The number of live births registered in 1938 was 2,286,962, a birth rate of 17.6 per thousand of population. This was a slight increase over 1937.

The maternal death rate for all causes decreased 11 per cent during the year 1938 (from 49 per 10,000 in 1937 to 43.5 per 10,000 in 1938). The combined rate for abortion and ectopic pregnancy decreased 16 per cent; the rate for puerperal sepsis, including phlegmasia

Maternal Deaths in 1938

	Number	Per Cent
Total deaths assigned to puerperal causes (International list numbers 140-150).....	9,953	100
Abortion and ectopic gestation.....	2,253	23
140—Abortion with septic conditions.....	1,380	
141—Abortion without mention of septic condition (to include hemorrhage).....	436	
142—Ectopic gestation.....	437	
Puerperal hemorrhage and other accidents of childbirth.....	2,638	27
144—Puerperal hemorrhage.....	1,320	
149—Other accidents of childbirth.....	1,338	
Puerperal septicemia and puerperal phlegmasia alba dolens, and so on.....	2,398	24
145—Puerperal septicemia (not specified as due to abortion).....	1,874	
148—Puerperal phlegmasia alba dolens, embolus, sudden death (not specified as septic).....	524	
Toxemias of pregnancy.....	2,521	25
146—Puerperal albuminuria and eclampsia.....	2,023	
147—Other toxemias of pregnancy.....	498	
Other accidents of pregnancy, other and unspecified conditions.....	123	1
143—Other accidents of pregnancy (not to include hemorrhage).....	104	
150—Other and unspecified conditions of the puerperal state.....	19	

alba dolens, and so on, decreased 12 per cent; the rate for all toxemias decreased 11 per cent, and the combined rate for puerperal hemorrhage and other accidents of childbirth decreased 7 per cent.

The accompanying table shows the number of maternal deaths in 1938 from several main groups of causes and the percentage of deaths in each of these groups.

Deaths from abortion and ectopic gestation in 1938 have been grouped together because they represent largely deaths occurring early in pregnancy. Deaths from accidents of pregnancy have been combined with those caused by puerperal hemorrhage because they are largely due to hemorrhage and shock associated with delivery. Deaths from phlegmasia alba dolens and other causes in this group are combined with those caused by puerperal septicemia because they are the result of infection. All toxemias are grouped together because it is impossible to separate satisfactorily each type of toxemia on the basis of information on death certificates. These are largely deaths from eclampsia, preeclampsia and nephritic toxemia (not including chronic nephritis, which is considered nonpuerperal). Deaths from accidents of pregnancy include deaths of undelivered women. These have been combined with the small number of deaths unclassified as to cause.

Approximately one fourth of the maternal deaths resulted from abortion or ectopic gestation, while three fourths are concerned with complications of late pregnancy, delivery or the puerperium.

From 1930 through 1934 the maternal mortality rate decreased only 12 per cent. From 1934 through 1938 the maternal mortality rate has decreased 25 per cent.

The decline of 14 per cent in 1937 as compared with 1936 and 11 per cent in 1938 as compared with 1937 represents a decrease of 23 per cent of the maternal mortality rate in the United States in the two year period 1937 through 1938. There would have been 5,370 more maternal deaths in 1938 if the maternal mortality rate of 1930 had applied in 1938.

The application of the best existing knowledge of maternal care to an increasing number of women is being rewarded by an extremely significant decrease in the number of maternal deaths. But further decrease is possible. To bring it about will require continued effort especially in those areas and among the special groups of the population where the rates are still far too high.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

LA FRANCE INHALATOR ACCEPTABLE

Manufacturer: The American-La France-Foamite Corporation, Elmira, N. Y.

The La France Inhalator is a portable apparatus designed for the administration of a mixture of oxygen and carbon dioxide in cases of asphyxia. Standard equipment includes a carrying case with two 16 cubic foot cylinders connected through valves to a rubberized cloth reservoir, which is in turn connected by rubber hose to two face masks and head harnesses. The inhalator may also be obtained with only a single cylinder, with which an outboard connection for use with 50 and 200 cubic foot cylinders is furnished. Accessories clipped in the case include tongue forceps, an oral screw, and two wrenches for making the necessary connections. Optional accessories include extra face pieces in different sizes, various sized cylinders filled with oxygen and carbon dioxide for outboard connection, and a case for carrying two spare 16 cubic foot cylinders. All the cylinders contain 7 per cent carbon dioxide. The weight is 56½ pounds and overall dimensions are 6½ by 15½ by 27 inches.

When in operation the gas flows from a cylinder through a valve to the manifold, where a pressure gage indicates in atmospheres the pressure in the cylinder. The gas then passes to the reducing valve, where a considerable reduction of pressure occurs, and on to the volume control valve. This flow control valve is attached to a radial dial graduated in liters of flow per minute. On the side of the flow control valve is a safety valve which provides escape of gas if for any cause the reducing valve should fail. From the control valve the gas passes to the breathing bag, where it expands to approximately atmospheric pressure and passes through a hose and face piece as required by the patient.

The cylinders are filled to a pressure of 145 atmospheres, or 2,175 pounds per square inch. One cylinder is to be used until empty, when a switch can be made to another one without discontinuing resuscitation. This is made possible by the functioning of the high pressure manifold provided with two valves. When the inhalator is to be used for only one patient, the second supply hose can be disengaged. The breathing of the patient can be observed by observing the expansion and contraction of the bag.

The face piece consists of three main parts: the face piece proper of cellulose acetate, an air-inflated rubber cushion, and the valve mechanism. The valve mechanism consists of three valves: one which opens on inhalation of the patient to admit

gas from the supply hose and closes on exhalation, a second which opens on exhalation and permits escape of the air to the outside, and a third which acts as a safety valve and allows air from the outside to be drawn into the face piece in case additional volume is needed beyond that supplied by the inhalator.

The inhalator was submitted to a qualified specialist for investigation. As a result of the Council investigation it was concluded that the device described as the La France Inhalator appears to be a well designed and constructed piece of equipment.

The Council voted to accept the La France Inhalator for inclusion on the Council's list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

MERCURIC SALICYLATE (See New and Nonofficial Remedies, 1939, p. 319).

Ampoules Mercuric Salicylate 0.065 Gm. (1 grain), 1 cc.: Each cubic centimeter contains mercuric salicylate 0.065 Gm. (1 grain) and quinine and urea hydrochloride 0.02 Gm. (½ grain) suspended in a sweet almond oil and lanum base.

Prepared by the Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

MERCURIC SUCCINIMIDE (See New and Nonofficial Remedies, 1939, p. 320).

Ampoules Mercury Succinimide 0.02 Gm. (½ grain), 1 cc.: Each cubic centimeter contains mercuric succinimide 0.02 Gm. (½ grain) and chlorobutanol not more than 0.008 Gm. dissolved in distilled water.

Prepared by the Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

POLLEN EXTRACTS-BARRY.—Liquids obtained by extracting the dried pollen of various species of plants.

Actions and Uses.—See general article, Allergenic Protein Preparations, New and Nonofficial Remedies, 1939, page 27.

Dosage.—See general article, Allergenic Protein Preparations, New and Nonofficial Remedies, 1939, page 27.

The following pollen extracts-Barry are marketed in packages of three vials, one containing 3 cc. of a solution having a potency of 100 pollen units per cubic centimeter, one containing 3 cc. of a solution having a potency of 1,000 pollen units per cubic centimeter, and one containing 5 cc. of a solution having a potency of 10,000 pollen units per cubic centimeter.

Prepared by the Barry Allergy Laboratory, Inc., Detroit, Mich. No U. S. patent or trademark.

Grass Mixture (Spring), (June Grass, Timothy, Red Top, Sweet Vernal Grass and Orchard Grass pollen extracts, in equal proportions); Ragweed (Large and Small Ragweed pollen extracts, in equal proportions).

Pollen extracts-Barry are prepared by grinding the dried pollen in a ball mill with a liquid containing 25 per cent glycerin, 0.275 per cent sodium chloride, 0.074 per cent sodium phosphate, 0.0285 per cent potassium dihydrogen phosphate and 0.4 per cent of cresol. The originally prepared solution presents a 3 per cent extract (30,000 pollen units per cubic centimeter), which is subsequently diluted to the desired concentration. The extract is subjected to Berkefeld filtration and is tested for sterility before dilution, after dilution and after filling, as required by the National Institute of Health. The finished liquid contains 8 per cent of glycerin and 0.4 per cent of cresol. The pollen unit corresponds to 0.001 mg. of dried pollen.

THEOBROMINE SODIUM ACETATE (See New and Nonofficial Remedies, 1939, p. 522).

Theobromine and Sodium Acetate-Mallinckrodt.—A brand of theobromine sodium acetate-N. N. R.

Manufactured by Mallinckrodt Chemical Works, St. Louis. No U. S. patent or trademark.

PENTOBARBITAL-SODIUM (See New and Nonofficial Remedies, 1939, p. 121).

Pentobarbital-Sodium-Gane.—A brand of pentobarbital-sodium-N. N. R.

Manufactured by Gane's Chemical Works, Inc., New York.

SULFANILAMIDE-LILLY (See New and Nonofficial Remedies, 1939, p. 464).

The following dosage forms have been accepted:

Pulverules Sulfanilamide-Lilly, 2 grains.
Pulverules Sulfanilamide-Lilly, 5 grains.

SATURDAY, MARCH 16, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE COURT OF APPEALS DECISION

Elsewhere in this issue appears a complete statement of the decision of the United States Court of Appeals for the District of Columbia in the case of the government versus the American Medical Association and various other organizations and persons. This statement summarizes the indictment and analyzes the case as being concerned with three main problems. These raise essentially the question as to whether or not there was a combination or conspiracy in restraint of trade as that term is used in the Sherman Act and whether or not the indictment was defective in form. There is a considerable discussion of the significance of the phrase "restraint of trade" and various previous legal decisions on the subject are cited, leading the court to the ultimate conclusion that the effect has been to enlarge the common acceptance of the word "trade" to cover all occupations in which men are engaged for a livelihood.

Although the court recognized the great public value of the work of organizations in raising standards of

conduct and skill, it was also of the opinion that medical societies may not legally effectuate restraints as far reaching as those which are charged. The court pointed out, of course, that the charge may be wholly unwarranted and the facts, when they are disclosed on the trial, may show an entirely different state of affairs. For the purpose of the decision in the present case, however, the court felt that it must consider the charge as though its verity were established, and if that point of view is taken the court felt that the offense is within the condemnation of the statute. The court then went into the question of corporations practicing medicine and said that, where a corporation operates a clinic, employs physicians and surgeons to treat patients and itself receives the fee, the corporation is unlawfully engaged in the practice of medicine. However, the court was of the opinion that, assuming the allegations of the indictment to be true, Group Health Association, Inc., was something different and, therefore, left open until the trial of the case the question whether or not Group Health Association, Inc., was illegally practicing medicine. Finally, the court took up the charges that were made as to the insufficiency of the indictment and reversed the opinion of the lower court on that point.

The repercussions from this decision by the Court of Appeals are already considerable; many of the opinions expressed indicate that this action is far from ending the consideration of this important subject. It becomes apparent at once that every labor as well as every other professional organization in the United States is intimately concerned with this decision. The *Washington Post* points out that it is well to remember that this opinion is not final, that the Supreme Court has not yet spoken and that, even should the Supreme Court sustain the Court of Appeals rather than Judge Proctor, it would still remain to be seen whether the persons charged in the indictment can be convicted under the indictment.

Between the time when the questions relating to the Group Health Association, Inc., were first raised and the time of this decision by the Court of Appeals, many changes have taken place in the structure of American medicine. The question of distribution of risk by the insurance method in meeting the costs of medical service and the relationship of organized medicine to that question can certainly not now be raised, since some fourteen state medical organizations and innumerable smaller medical units in medical organization are themselves engaged in such plans. The Group Health Association, Inc., seems to be functioning, at least to its own satisfaction, in the District of Columbia, and the Medical Society of the District of Columbia itself has a plan for medical service which is also in the status of an operating experiment.

The decision as to whether or not medicine is a profession or a trade is exceedingly important not only as relates to this case but also in relationship to many another piece of legislation of utmost concern to every

scientific, professional, educational and similar organization in the United States. There are numerous problems associated with the laws regulating taxes, social security, licensure and innumerable other rights and privileges involved in medical practice which depend greatly on the distinction between the practice of a profession and a trade or other occupation.

Thus the decisions made by the courts in relationship to the questions that have been raised are basic and far reaching in their ultimate effect on every organized professional body in this country. The principle at issue involves the right of any professional group to regulate its own conduct and even to determine its own membership. As even the Court of Appeals recognized, the existence of such organized bodies has served vastly for the benefit of the people, achieving objectives in raising the standards of education and of service far beyond those which might have been achieved by any other sort of effort, including no doubt even efforts that might be made by various legally constituted or governmental agencies.

Perhaps the thought is in itself a reflection on our present system of social organization, but it is interesting to realize that the determination of the issue on which the Court of Appeals has just made a pronouncement and on which the Supreme Court has yet to rule is of little or of no importance as relates to the provision of medical service at low cost for large numbers of people. It may be of vast significance, however, in serving to bring about revolution in the existing social organization through the breaking down of established bodies. Such a revolution Mr. Thurman Arnold seems to desire if one interprets correctly his book "The Folklore of Capitalism." The issue involved is thus fundamentally whether or not our democracy as now existing is capable of meeting the needs of civilized man or whether some completely new social scheme is going to be necessary to satisfy those officials of government who have taken on themselves the task of creating a new order.

UNITED STATES INFANT AND MATERNAL MORTALITY RATES

Maternal mortality rates of the United States have been reported and discussed for several years apparently to conjure conclusions designed to throw discredit on the medical profession. The publicity of the Interdepartmental Committee repeatedly charged that there had been no significant decline in the rate of maternal mortality "in the registration area" of the United States during the last twenty years. Credence was given to this statement by the fact that the "registration area" was constantly changing as new states, usually with higher mortality rates, were admitted to the area. Since 1931 only two new states (South Dakota in 1931 and Texas in 1932) have been added to the birth registration area. Only in more recent years have any statistics been available for a uniform registration area. In 1931 the death rate for puerperal causes in the registration

area was 6.6 per thousand live births; in 1938 it was 4.4.¹ This is a decline of a little over 30 per cent in eight years.

Again and again the propagandists alleged that the United States was lagging behind most of the other modern nations in its maternal mortality rate. This conclusion was reached by comparing nations, some of which were not larger than some counties in the United States and with an exclusively white population less than that of some American cities, with the entire continental United States with its wide diversity of population, including 10 per cent of Negroes with a peculiarly high maternal mortality rate. Vital statisticians have frequently pointed out that the only fair comparisons of mortality statistics would be between individual states and European nations. The latest reports available from most European nations are for 1937.² In that year the maternal death rates for the countries from which invidious comparisons have previously been made were Australia 4.6, Canada 4.8, Chile 9.9, Germany 4.7, New Zealand 3.6, the Netherlands 2.5, Sweden 3.2. In that year the United States registration area had a maternal mortality rate of 4.9. Much more significant is the fact that in twenty-eight states of the United States the maternal death rate in 1938 was below 4.0. In the following states the maternal death rate was below 3.0: Connecticut 2.6, Minnesota 2.8, North Dakota 2.4, Rhode Island 2.8, Wisconsin 2.9.

Infant mortality, generally considered the most sensitive index of health conditions, shows even more significant declines. This rate is the number of deaths under 1 year in each thousand live births. In 1938 the infant death rate in Great Britain was 53 per thousand live births. In the United States it was 50.5 in 1938, and 48.2 was the provisional rate in 1939. The rate for the white race in the United States for 1939 was 47. In some of the more comparable larger nations the infant death rate in 1937, the latest year for which the Annual Epidemiological Report of the League of Nations gives figures, was as follows: Canada 76, Germany 64, England and Wales 58, the Netherlands 38, Sweden 46. The infant death rates for seven states of the Union in 1938 with the provisional rates for 1939 were as follows:³

State	1938	1939
Connecticut	36.3	35.5
Indiana	42.5	38.7
Minnesota	38.8	35.8
Nebraska	36.4	33.2
Oregon	39.2	34.7
South Dakota	43.8	37.6
Washington	38.7	38.1

The infant mortality rate for Chicago in 1938 was 33.9 and in 1939 it was 31.3. For New York City it was 38.3 in 1938 and 37.1 in 1939.

As far as any information now available reveals, these infant death rates are the lowest for any com-

parable population in the world. In the two European nations with the lowest death rates, the Netherlands has only a system of cash benefits in its system of compulsory sickness insurance and Sweden has only a voluntary system of sickness insurance.

RESPIRATORY ALLERGY IN CHILDREN AND TONSILLECTOMY

The simulation of diseases by pseudosyndromes may confuse the clinical picture, mislead diagnosis and contribute to therapeutic error. Frequent colds, sinusitis, bronchitis and recurrent pneumonias in children are generally considered infectious and related to reservoirs of infection in the tonsils. Consequently tonsillectomy is often prescribed. According to *Public Health Reports* 1,235,000 tonsillectomies are performed each year in the United States. Hansel and Chang¹ now point out that signs and symptoms of respiratory abnormality in the upper tract may frequently be due to an allergic factor simulating the infectious etiology discoverable in the majority of such cases. Hence the proper diagnosis of respiratory diseases centers for them in careful clinical and laboratory examinations that are based on the threefold possibility of an allergic agent, an infective agent and an allergic phase obscured by acute or chronic infections. Ultimate diagnostic determination is achieved by a differential test.

In an examination of 200 unselected children between the ages of 3 and 16, of whom 104 were boys and ninety-six girls, observed at the clinic of the Washington University School of Medicine in St. Louis in July, August and September 1938, the authors discovered twenty-six cases of nasal allergy, equivalent to 13 per cent of the whole group. In only half of the twenty-six were local nasal symptoms typical. A positive family history of allergy was noted in eleven (42 per cent). Only fourteen (54 per cent) showed typical pallor or edema of the nasal mucosa. Seventeen of the twenty-six had had an acute infectious disease (such as measles, scarlet fever or pertussis). Six of the twenty-six had hay fever when examined. Final diagnosis was based on the demonstration of eosinophils in the nasal secretions. The authors believe that, in the absence of hay fever and asthma, nasal allergy and allergic bronchitis frequently elude diagnosis and that tonsillectomy is often recommended because allergic symptoms are mistaken for those of an infectious origin.

Hansel and Chang estimate that about 160,000 allergic patients (13 per cent of the annual total of more than a million and a quarter of tonsillectomized persons) are unnecessarily subjected to tonsillectomy every year. They note sequels of tonsillectomies performed on allergic children, such as excessive regrowth of lymphoid tissue in the tonsillar fossae and aggravation of allergic symptoms. Children with nasal allergy, allergic involvement of the sinuses, allergic bronchitis and

allergic pneumonia are not favorably influenced by tonsillectomy. They caution against the removal of tonsils and adenoids in allergic children during hay fever and against recourse to tonsillectomy with the idea of alleviating allergic symptoms. Indications for tonsillectomy in children with nasal allergy should be the same as those in children without nasal allergy.

Current Comment

FIRST DAY SALE OF THE CRAWFORD LONG MEMORIAL STAMP

A new postage stamp commemorating Dr. Crawford W. Long as the discoverer of ether anesthesia will be issued by the Post Office Department, April 8. The first day sale of the two-cent stamp will be held at Jefferson, Ga., where ether was first used as an anesthetic for a surgical operation, March 30, 1842. This operation was for the removal of a tumor from the neck of James M. Venable. Four witnesses were present, one of whom was Dr. Edward S. Rawls. Dr. Long discussed the possibilities of ether as an anesthetic with his fellow physicians. The Universities of Georgia and Pennsylvania, where Dr. Long studied, have provided memorials, and monuments have been erected in his native Danielsville and at Jefferson, Ga. A hospital in Atlanta has been named in honor of Dr. Long, and on March 30, 1926, his likeness in marble was unveiled in Statuary Hall in the Capitol Building in Washington. Members of the profession can arrange for first day cancellation of the special stamp on official covers arranged by citizens of Jefferson by writing to Mrs. H. I. Mobley, cachet chairman, Jefferson, Ga.

SURGEON GENERAL'S LIBRARY

Constantly in abeyance for almost a decade has been the proposal to erect a new building for the Army Medical Library and Museum in Washington, D. C. Now the path has been cleared, a site has been found near the Library of Congress, and all that is necessary is the final appropriation. The collection of medical works in the Army Medical Library is one of the finest in the world; indeed, it is thought by many to deserve the absolute superlative. Yet it is housed today in an ancient structure, a veritable fire trap, in which an accident of some type might bring about a catastrophic destruction of material which could never be replaced. Certainly if ever a need existed for expenditure of money for some real purpose, it exists in relation to the necessity for building a new home for this invaluable scientific medical collection. Recently the Librarian of Congress, Archibald MacLeish, was asked his opinion of the Army Medical Library. His reply was "The Surgeon General's Library is one of the greatest special collections of books ever put together, if not indeed the greatest, and its present lack of housing holds tragic possibilities for American learning and for the good repute of American learning." In the very near future Congressional hearings will be held on this project. Every physician may well afford to lend his voice to the appeal for immediate action.

ORGANIZATION SECTION

COURT OF APPEALS UPHOLDS A. M. A. INDICTMENT

UNITED STATES COURT OF APPEALS
FOR THE DISTRICT OF COLUMBIA
No. 7488

UNITED STATES OF AMERICA, APPELLANTS,
v.
AMERICAN MEDICAL ASSOCIATION, A CORPORATION,
THE MEDICAL SOCIETY OF THE DISTRICT OF
COLUMBIA, A CORPORATION, HARRIS COUNTY
MEDICAL SOCIETY, AN ASSOCIATION,
ET AL., APPELLEES

Appeal from the District Court of the United States
for the District of Columbia

(Argued January 12, 1940 Decided March 4, 1940)

Thurman Arnold, Assistant Attorney General, and
John Henry Lewin, Special Assistant to the Attorney
General, both of Washington, D. C., for appellants.

William E. Leahy, *Seth W. Richardson*, *John E.
Laskey*, *Charles S. Baker*, all of Washington, D. C., and
Edward M. Burke, of Chicago, Illinois, for appellees.

Before GRONER, C. J., and MILLER and VINSON, JJ.

GRONER, C. J.: This appeal is taken from a judgment of the United States District Court sustaining a demurrer to an indictment for conspiracy in restraint of trade in the District of Columbia, in violation of Sec. 3 of the Sherman Anti-trust Act.¹

The main purpose of the conspiracy as shown in the indictment was to impair or destroy the business and activities of Group Health Association, Inc., which had been organized in 1937 as a nonprofit cooperative association for the provision of medical care and hospitalization to its members and their dependents. The indictment is very long but, summarized, charges as follows:

Group Health is an association of employees of certain executive departments of the Government employed in the District of Columbia, 80 per cent earning annual incomes not over \$2,000. The association provides medical care and hospitalization to its members and their dependents on a risk sharing prepayment basis. Its funds are collected monthly in the form of dues. Medical care is provided by its medical staff, consisting of salaried physicians under the sole direction of a medical director. It provides a modern clinic and defrays, within certain limits, the expenses of hospitalization of its members and their dependents. The personal relationship ordinarily existing between doctor and patient exists between Group Health doctors and Group Health patients.

Defendant American Medical Association is a corporation, with a membership of 110,000 out of the total of 145,000 physicians in the United States. It is the only important national society representative of the medical profession in the country. It maintains a

"Bureau of Medical Economics," which has taken a leading part in carrying out the Association's policy of discouraging and suppressing group medical practice on a risk sharing prepayment basis.

Defendant The Medical Society of the District of Columbia is a constituent society of American. Defendant Harris County Medical Society is a component society of American. Members of constituent and component societies are *ipso facto* members of American. Washington Academy of Surgery is an unincorporated association with its office in the District of Columbia. Of the individual defendants, five were officers of American, and the others members of District Society, most of the latter being officers or else members of the executive and hospital committees of the Society or members of the regular staffs of Washington City hospitals. American Association and District Society possess power to exclude a doctor, disapproved by them, from attending and treating his patients in the Washington hospitals, which include all the hospitals in the District of Columbia in which private patients may be treated by doctors. By enforcing their rules of ethics and expelling members, they may deprive them of the essential privilege of consultation with other members. By granting or refusing approval of hospitals, they can control the ability of hospitals to obtain interns, and by threatening hospitals with the exercise of this power they may control the members of medical staffs in each. To carry out these powers, on November 3, 1937, District Society adopted the following resolution:

WHEREAS, The Medical Society of the District of Columbia has an apparent means of hindering the successful operation of Group Health Association, Inc., if it can prevent patients of physicians in its employ being received in the local private hospitals; and

WHEREAS, The Medical Society of the District of Columbia has no direct control over the policies of such hospitals as determined by their lay boards of directors, except through its control of its own members serving on their medical staffs; and

WHEREAS, Conflicts between the Medical Society of the District of Columbia and any local hospitals arising from an attempt to enforce the provisions of chapter IX, article IV, section 5, of its constitution should be assiduously avoided, if possible, because of the unfavorable publicity that would accrue to its own members; therefore, be it

Resolved, That the Hospital Committee be, and is hereby, directed to give careful study and consideration to all phases of this subject and report back to the Society, at the earliest practicable date; its recommendations as to the best way of bringing this question to the attention of the medical boards and boards of directors of the various local hospitals in such a manner as to insure the maximum amount of practical accomplishment with the minimum amount of friction and conflict.

Subsequently, the conspiracy was discussed at meetings held by members and committees of District Society, with the purpose of "hindering" Group Health from procuring and retaining on its medical staff quali-

1. 26 Stat. 209, 15 U. S. C. 3.

fied doctors by threatening with disciplinary action any members of District Society who should either join Group Health's staff or consult with physicians on its staff, and with the purpose of hindering and obstructing members of Group Health from obtaining access to hospital facilities and obstructing the doctors on its staff from treating and operating on patients in Washington hospitals, and for the purpose of inducing Washington hospitals to boycott Group Health and its doctors. A "white list" of approved organizations, groups and individuals was circulated, with the name of Group Health omitted—all for the purpose of threatening with disciplinary action any member of the District Society who worked for Group Health or consulted with any doctor on its staff and any hospital which admitted any Group Health doctor to its courtesy staff—the general purpose of the conspiracy being to restrain doctors in the District of Columbia in the pursuit of their calling and to restrain the hospitals in the operation of their business and to destroy Group Health in the performance of its functions. Disciplinary action was taken against two District Society members on Group Health's staff. One was induced to resign from the staff, the other was expelled from the society. Harris County Society opened disciplinary action against one of its members on the staff. District Society opened disciplinary action against a specialist who consulted with a Group Health doctor. Demand was made on the hospitals that they receive only members of the American Medical Association on their staffs. On recommendation of Washington Academy of Surgery, a surgeon was excluded from hospital staffs principally because he was working for Group Health. By threatening to deprive another doctor of courtesy staff privileges, defendants induced a Group Health doctor to resign his position.

The conspiracy is charged to have had as its background the long continued policy of opposition on the part of American Medical Association to risk sharing plans for medical service, growing out of the fear of its members of business competition from doctors connected with such organizations. Each defendant is charged to have knowingly participated in the formation and furtherance of the plan pursuant to the common purpose.

The several defendants demurred on a number of grounds, attaching not only the substance but the form of the indictment.

The District Court sustained the demurrer (1) because the practice of medicine is not a trade within the meaning of sec. 3 of the Sherman Act; (2) because the indictment is vague and uncertain and fails to charge clearly commission of any crime.

The United States has appealed under the provisions of the Act of March 3, 1901, ch. 854, 31 Stat. 1225, 1341, D. C. Code 1929, tit. 6, sec. 355.

The case divides itself into three main problems:

1. Does the indictment charge a combination or conspiracy in restraint of "trade" as that term is used in sec. 3 of the Sherman Act?

2. If it does, is the restraint charged an unreasonable one which would be illegal under the act?

3. Is the indictment defective in form?

Sec. 3 of the statute reads as follows:

Every contract, combination in form of trust or otherwise, or conspiracy, in restraint of trade or commerce in . . . the

District of Columbia . . . is hereby declared illegal. Every person who shall make any such contract or engage in any such combination or conspiracy, shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by fine not exceeding five thousand dollars, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

The trial court was of opinion that the practice of medicine and the business of Group Health and the hospitals do not constitute "trade" within the intent of the statute. The question is new, at least to the extent that there is no case in which, in the circumstances existing here, it has been decided, but a careful consideration of the language of the act, its legislative background and the various statements of the Supreme Court concerning the source from which the congressional purpose may be gathered, leads us to conclude the trial court was in error.

The phrase "restraint of trade" had its genesis in the common law, and its legal import and significance is declared again and again in the decisions of English courts, both before and after the date of our independence, as well as in American decisions in many of the states. The Supreme Court has said that Congress passed the Sherman Act with this common law background in mind. And so in the *Standard Oil* case,² Chief Justice White traces its use to the common law. Thus, at the top of page 51, he says:

It is certain that those terms, at least in their rudimentary meaning, took their origin in the common law and were also familiar in the law of this country prior to and at the time of the adoption of the act in question.

And again:

It is certain that at a very remote period the words "contract in restraint of trade" in England came to refer to some voluntary restraint put by contract by an individual on his right to carry on his trade or calling. Originally all such contracts were considered to be illegal, because it was deemed they were injurious to the public as well as to the individuals who made them.

And still again (p. 59):

Let us consider the language of the first and second sections guided by the principle that where words are employed in a statute which had at the time a well known meaning at common law or in the law of this country they are presumed to have been used in that sense unless the context compels to the contrary.

In view of the common law and the law in this country as to restraint of trade, which we have reviewed, and the illuminating effect which that history must have under the rule to which we have referred, we think it results:

(a) That the context manifests that the statute was drawn in the light of the existing practical conception of the law of restraint of trade, because it groups as within that class, not only contracts which were in restraint of trade in the subjective sense, but all contracts or acts which theoretically were attempts to monopolize, yet which in practice had come to be considered as in restraint of trade in a broad sense.

Similar statements are to be found in *United States v. American Tobacco Co.*, 221 U. S. 106, 179; *Nash v. United States*, 229 U. S. 373, 377; *Eastern States Retail Lumber Dealers Ass'n v. United States*, 234 U. S. 600, 610; *United States v. Addyston Pipe & Steel Co.*, 85 Fed. 271, 278-9, aff'd 175 U. S. 211;

2. 221 U. S. 1, 50-60.

United States Tel. Co. v. Central Union Tel. Co., 202 Fed. 66, 70. There are like statements in the debates in Congress. 21 Con. Rec. 3146, 3148, 3152. And see Judge Taft's opinion in the *Addyston Pipe Co.* case, where he said:

It is certain that, if the contract of association which bound the defendants was void and unenforceable at the common law because in restraint of trade, it is within the inhibition of the statute. . . .

In *Leonard v. Abner-Drury Brewing Co.*, 25 App. D. C. 161, 174, we said as much with respect to sec. 3 of the act. It must, therefore, be considered that the scope of "restraint of trade" in sec. 3 is to be measured by its use at common law.

The common law rule was applied principally to contracts whereby a man promised not to engage in his occupation, including the practice of medicine, and in many English cases such a restraint on the practice of medicine was described as a contract in "restraint of trade." Defendants contend, however, that whatever the English usage, the word "trade" had in this country a definite and well understood meaning, and as used in the Sherman Act was confined to transportation and the buying, selling, or exchanging of commodities and in any case was not intended to apply to any employment or business carried on by the "learned professions." The determination of this aspect of our problem lies in the answer to this proposition.

In *Atlantic Cleaners & Dyers v. United States*, 286 U. S. 427, it was held the words "trade" and "commerce" had a broader meaning in sec. 3 of the act than in sec. 1 and that, under the paramount power of Congress to legislate for the District of Columbia, the use of the words in that section should be held to embrace the exercise of that paramount power to its fullest extent.—

We are, therefore, free to interpret § 3 dissociated from § 1 as though it were a separate and independent act and, thus viewed, there is no rule of statutory construction which prevents our giving to the word "trade" its full meaning, or the more extended of two meanings, whichever will best manifest the legislative purpose.

(p. 435.)

Cleaners and dyers in the District had formed a combination to keep up prices, and the United States brought suit to enjoin the agreement and reestablish competition. The defendants insisted their arrangement was not a violation of sec. 3 because they were not engaged in trade, relying on *National League Clubs v. Federal Baseball Clubs*, 50 App. D. C. 165, 168, holding that "trade" connotes the transfer of something, "whether it be persons, commodities, or intelligence from one place or person to another." The opinion ignored the citation, doubtless because the baseball case was brought under section 1—the interstate commerce section of the act—and Justice Sutherland, who wrote the opinion, rejected this restricted definition as applied to sec. 3. In support of a definition to include the cleaning business, he quoted from Justice Story's opinion in *The Nymph*, 18 Fed. Cas. 506, No. 10,388:

. . . the word "trade" is often and, indeed, generally used in a broader sense, as equivalent to occupation, employment, or business, whether manual or mercantile. Wherever any occupation, employment, or business is carried on for the purpose of profit, or gain, or a livelihood, not in the liberal arts or in the learned professions, it is constantly called a trade.

The learned trial judge felt that the italicized words should be regarded as an authoritative statement of the Supreme Court that the professions were not trades and therefore not within the intent of the act. But we think this by no means follows. The court had before it only the problem whether "trade" was broad enough to include the cleaning and dyeing of clothes, and held it was. To reinforce its reasoning, the court quoted language which happened to exclude the learned professions, but this limitation was not responsive to the question at hand and was purely casual, and in the circumstances ought not, we think, to be regarded as a proper guide in deciding the important question in this case.

The same might be said of *Fed. Trade Com. v. Raladam Co.*, 283 U. S. 643, where Justice Sutherland said that physicians followed a profession and not a trade. He was dealing with a case of interstate commerce and simply pointed out the obvious fact that doctors were not in the patent medicine trade, and could not be in competition with vendors of medicine within the sense of the Trade Commission Act. There, he was using the word "trade" in its narrowest sense, a restriction which, as we have seen, he later rejected in regard to sec. 3 of the Sherman Act.

The common law cases which shed light on the question are all of a type. A physician, a surgeon, or a dentist has an established practice in a community. He takes on an assistant, or a partner, or else sells his practice to another of his own profession. In the first two cases he wants to protect his own practice, and in the third case the buyer wants protection from subsequent competition by the seller. Consequently, the assistant, or partner, or seller, as the case may be, promises for a consideration not to practice within the community or within a designated distance. This promise is a voluntary restraint on the pursuit of a man's calling, and in the circumstances, the public policy described by Chief Justice White in the *Standard Oil* case becomes involved. The restraint will be upheld only if it (1) is partial; (2) is made for an adequate consideration; and (3) is reasonable as a protection of the good will of another's professional practice. *Holbrook v. Waters*, 9 How. Prac. (N. Y.) 335.

In England such a contract was constantly referred to as involving the doctrine of "restraint of trade." See *Davis v. Mason*, 5 T. R. 118, 101 Eng. Rep. 69; *Hayward v. Young*, 2 Chitty 407; *Atkins v. Kinnier*, 4 Ex. 776, 154 Eng. Rep. 1429; *Gravelly v. Barnard*, L. R. 18 Eq. 518. In all of the above the lawyers who raised the point and the judges who passed on it referred to the public policy as the doctrine of restraint of trade, contracts in restraint of trade, or in partial restraint of trade. In *Horner v. Graves*, 7 Bing. 735, 131 Eng. Rep. 284, defendant had promised not to practice within 100 miles of York. The opinion of Tindall, C. J., recognizes the occupation of surgeon-dentist as a profession, but in considering the validity of the contract he uses the words "profession," "business" and "trade" interchangeably.

American cases decided before passage of the Sherman Act recognize and follow the reasoning of these English cases. See *Cook v. Johnson*, 47 Conn. 175, which involved a dentist's contract. There the court said that it belonged to the class of contracts in restraint of trade. To the same effect, see *Haldeman v. Simon*.

The charge, stated in condensed form, is that the medical societies combined and conspired to prevent the successful operation of Group Health's plan, and the steps by which this was to be effectuated were as follows: (1) to impose restraints on physicians affiliated with Group Health by threat of expulsion or actual expulsion from the societies; (2) to deny them the essential professional contacts with other physicians; and (3) to use the coercive power of the societies to deprive them of hospital facilities for their patients. Sufficient facts are stated to demonstrate that, unchecked, this exertion of power will necessarily accomplish the abandonment of the cooperative plan of medical service, as well as destroy the livelihood of dissident doctors, because the general restraint thus applied would make impossible the continued operation of the one or the successful practice of medicine by the others.

Defendants say that what they are charged with doing amounts to no more than the regulation of membership in the society and the selection of the persons with whom they wish to associate; that under their rules disobedient members may lawfully be disciplined and that discipline does not amount to unreasonable restraint. This may very well be true, and in considering the contention we are not unmindful of the importance of rules of conduct in medical practice, rules which can best be made by the profession itself. We recognize, in common with an almost universal public opinion, that in the last half century, through this means, the quack and the charlatan have been largely deprived of the opportunity of preying on the unfortunate and the credulous. We also recognize that in personal conduct and in professional skill the rules and canons, so established, have aided in raising the standards of medical practice to the advantage of the whole country. We are mindful of a generally known fact that under these rules and standards there has developed an *esprit de corps* largely as a result of which the members of the profession contribute a considerable portion of their time to the relief of the unfortunate and the destitute. All of which may well be acknowledged to their credit. Notwithstanding these important considerations, it cannot be admitted that the medical profession may through its great medical societies, either by rule or disciplinary proceedings, legally effectuate restraints as far reaching as those now charged. "An act harmless when done by one may become a public wrong when done by many acting in concert, for it then takes on the form of a conspiracy, and may be prohibited or punished, if the result be hurtful to the public or to the individual" against whom it is directed. *Eastern States Retail Lumber Dealers Ass'n v. United States*, 234 U. S. at p. 614. If there is any justification for the restraint, so as to make it reasonable as a regulation of professional practice, it must be shown in evidence as a defense, since it does not appear in the indictment.

Restraints prohibited by sec. 3 of the Sherman Act are those which unduly hinder a person from employing his talents, industry, or capital in any lawful undertaking and thus keep the public from receiving goods and services as freely as it would without such restraints. Enough has been said to show that the restraint here charged would restrict the common liberty of Group Health, the doctors, and the hospitals from engaging in the pursuit of their respective functions. If on the trial the charge of confederation to this end is sustained, defendants' method of reaching their objective may be thereby defeated, but if the objective is wise—as they

insist—they still have left, as was said by the English judge in the *Pratt* case, the safer and more kindly weapons of legitimate persuasion and reasoned argument. In the proper use of these, much, as we think, may be accomplished to avoid the growing movement toward professional regimentation. Or, this opportunity neglected, members of the medical associations in the District of Columbia perhaps may find in sec. 3, as we construe it, their only protection in the right to practice on a fee for service basis.

In the light of what has been said, we consider the numerous cases involving the reasonable operations of trade associations and trade unions as inapplicable. Organizations and rules which have as their purpose the improvement of conditions in any particular trade or occupation, and the regulation of relations between traders, are, as we have just pointed out, beneficial rather than detrimental to the public interest. But when these same organizations go so far as to impose unreasonable restraints on the operations in their field, they become subject to the prohibition of the Sherman Act. *Sugar Institute v. United States*, 297 U. S. 553, 597-600.

Appellees rely on the following state court decisions: *Harris v. Thomas* (Texas Civ. App.), 217 S. W. 1068; *Porter v. King County Medical Society*, 186 Wash. 410, 58 Pac. 2d 367; *Irafin v. Lorio*, 169 La. 1090, 126 So. 669; *Weyrens v. Scotts Bluff County Medical Society*, 133 Nebr. 814, 277 N. W. 378; *Strauss v. Marlboro County Hospital*, 185 S. C. 425, 194 S. E. 65; *Newton v. Board of Commissioners*, 86 Colo. 446, 282 Pac. 1068; *McDonald v. Massachusetts General Hospital*, 120 Mass. 432; *Branagan v. Buckman*, 67 Misc. 242, 122 N. Y. Supp. 610; and *Olander v. Johnson*, 258 Ill. App. 89. They insist these cases sustain the view that disciplinary action taken against one of their number by an association of physicians pursuant to its canons of ethics is permissible and does not violate the common rights either of the individual or of the public. We have examined these cases and are of opinion that, with the exception of the *Porter* and *Weyrens* cases, none is apposite. Those two cases do tend to sustain the actions of medical societies in their attempt to control the scale of medical fees, but in so far as they hold such action to be lawful and deny any right to the injured individual to obtain redress, we cannot accept them as binding or even persuasive authority in the decision of what is or is not lawful under the Sherman Act. The doctrine of restraint of trade was not involved in either case. In the *Weyrens* case, an expelled physician asked a court to order his reinstatement in his medical society, before he had exhausted his remedies within the organization. In the *Porter* case, a layman lost his job because defendants had induced his employers to close their business. The lawfulness of the inducements was considered solely in the light of what a society might do with respect to its membership and selfish motives were deemed immaterial. In our view, the Sherman Act must be applied with respect to public interests, and this raises broader issues than these two cases contain.

At the risk of tedious repetition, we repeat that the charge made here, and for the purposes of the demurrer admitted, is that the societies sought to restrain an association of persons of modest means from receiving medical services at lower cost and to coerce doctors and hospitals to this end. The charge may be wholly unwarranted and the facts, when they are disclosed on the

trial, may show an entirely different state of affairs, but for present purposes we must take the charge as though its verity were established; and in that light, it seems to us clear that the offense is within the condemnation of the statute. It certainly cannot be doubted that Congress intended to exert its full power, in the public interest, to set free from unreasonable obstruction the exercise of those rights and privileges which are a part of our constitutional inheritance, and these include immunity from compulsory work at the will of another, the right to choose an occupation, the right to engage in any lawful calling for which one has the requisite capacity, skill, material, or capital, and thereafter the free enjoyment of the fruits of one's labors. Congress undoubtedly legislated on the common law principle that every person has individually, and that the public has collectively, a right to require the course of all legitimate occupations in the District of Columbia to be free from unreasonable obstructions; and likewise in recognition of the fact that all trades, businesses and professions, which prevent idleness and exercise men in labor and employment for the benefit of themselves and their families and for the increase of their substance, are desirable in the public good and any undue restraint upon them is wrong and is immediate and unreasonable and, therefore, within the purview of the Sherman Act. For illustrations of this principle, see *Loewe v. Lawlor*, 208 U. S. 274; *Eastern States Lumber Dealers Assn. v. United States*, 234 U. S. 600; *Lawlor v. Loewe*, 235 U. S. 522; *Duplex Printing Co. v. Deering*, 254 U. S. 443; *Bedford Cut Stone Company v. Stone Cutters Association*, 274 U. S. 37; *Montague v. Lowry*, 193 U. S. 38; *United States v. Brims*, 272 U. S. 549.

In the *Eastern States* case, an association of retail lumber dealers, in a desire to protect their local retail trade against competition by wholesalers selling to consumers within local territory, agreed to report any information received by any one of them showing such sales by any wholesaler. This information when obtained was sent to the secretary of the association and if, upon investigation by a board, it was found to be true, the name of the wholesaler was placed on a list distributed among all the members. The purpose was to induce all retailers who received the list to withhold patronage from the offender. The Supreme Court held that the circulation of the list was in unreasonable restraint of commerce, since it influenced retailers with no personal grievance to cease trading with the offender.

... the trade of the wholesaler with strangers was directly affected, not because of any supposed wrong which he had done to them, but because of the grievance of a member of one of the associations, who had reported a wrong to himself, which grievance when brought to the attention of others it was hoped would deter them from dealing with the offending party.

This practice, the court said, brought the act within the prohibited class of undue and unreasonable restraints. If what was proved there was unreasonable, what is charged here is so in a larger degree, since the effect in the present case on the activity to be restrained is more serious as well as more far reaching.

Defendants contend as a subsidiary argument that, without regard to whether the restraint would or would not be an illegal act ordinarily, it is not so in the present instance for the reason that Group Health as a corporation is itself illegally practicing medicine. The United States District Court decided to the contrary

some time ago, in a suit for declaratory judgment.⁵ There was no appeal, and the question, so far as we are concerned, may be said to be open. On this demurrer it is unnecessary, and indeed undesirable, that we should pass on it except to decide whether, as described in the indictment, Group Health is necessarily violating the law.

The practice of medicine in the District of Columbia is subject to licensing and regulation and, we think, may not lawfully be subjected "to commercialization or exploitation." As was well said in *People v. United Medical Service*, 362 Ill. 442, 200 N. E. 163, the practice of medicine requires something more than the financial ability to hire competent persons to do the actual work. And so it has been held under varying conditions, speaking generally, that where a corporation operates a clinic or hospital, employs licensed physicians and surgeons to treat patients, and itself receives the fee, the corporation is unlawfully engaged in the practice of medicine. This is true because it has been universally held that a corporation as such lacks the qualifications necessary for a license, and without a license, its activities become illegal.⁶ It has also been said that the relationship of doctor and patient, well recognized in the law, would be destroyed by such an arrangement. On the other hand, some courts have drawn a distinction between practicing medicine and merely furnishing medical services.⁷

But in all the cases we have examined in which the practice has been condemned, the profit object of the offending corporation has been shown to be its main purpose, and in no case were the circumstances precisely like those described in the indictment, i. e., a nonprofit organization, conducted so that the proper doctor and patient relationship is preserved; prospective patients organized only for the purpose of providing a clinic and paying doctors and hospital service out of members' dues; a plan designed not to interfere with the doctor's loyalty to his patient so as to commercialize medicine in a way contrary to the best interests of patient or practice, or to subject the physician to the corporation's control and make his practice a corporate act. As thus described, it is no more than a group of persons, under corporate organization, contributing stated sums of money monthly for the payment of prospective medical services to the extent they may be required. In these respects, it differs from the medicine-practicing corporations which in many of the states have been held to be illegal. Without more, there-

5. *Group Health Assn., Inc. v. Moar*, 24 F. Supp. 445.

6. Cases holding that a corporation was practicing medicine, or dentistry, or surgery illegally are: *McMundo v. Getter*, (Mass.) 10 N. E. 2d 139 (employer was vendor of eye glasses prescribed by doctor); *Pacific Insurance Co. v. Carpenter*, 10 Cal. App. 2d 592, 52 P. 2d 992 (employer was in the insurance business, making money out of premium profits); *State v. Boston System Dentists*, (Ind.) 19 N. E. 2d 919 (employer was a corporation authorized to engage in practicing dentistry and the salaried dentists were its servants for hire); *Winstow v. Kansas State Board*, 115 Kan. 450, 223 P. 308 (employer incorporated for the purpose of maintaining dental quarters, furnishing services of dentist, and selling dental equipment); *State v. Bailey Dental Co.*, 221 Iowa 781, 234 N. W. 260 (corporation maintaining dental offices); *People ex rel. Lederman v. Warden of City Prison*, 168 App. Div. 240, 152 N. Y. Supp. 977 (drug store employed physician to give free medical attention to its customers); *People v. Painless Parker Dentist*, 85 Colo. 304, 275 Pac. 928 (corporation furnishing dental services through its employee for its profit); *People v. United Medical Service*, 362 Ill. 442, 200 N. E. 157 (corporation furnishing medical service on a flat fee to customers for its own profit). See also *Hannon v. Siegel-Cooper Co.*, 167 N. Y. 241, 60 N. E. 597; cf. *In re Co-operative Law Co.*, 198 N. Y. 479, 92 N. E. 15.

fore, than now appears, we are unable to say that Group Health is illegally practicing medicine.

We come finally to the question whether the indictment is sufficient in form. The learned trial judge was of opinion it was not. He thought the indictment afflicted with vague and uncertain statements and lacking in material facts. On the argument in this court, appellees' contentions may be summarized as follows: that the indictment is generally indefinite, full of conclusions and opinions, and does not set out the offense with particularity; the allegations as to the background of the conspiracy and the power of the medical organizations are irrelevant; the character of Group Health and the business of the Washington hospitals are not properly shown; there is a variance between the risk sharing plans described in the background of the conspiracy and the description of the activities of Group Health; the averments as to the principles of medical ethics and the operation of the societies are insufficiently stated; there are no facts stated as to restraints on hospitals; the averment as to dates is insufficient; and there is no charge against the individual defendants.

We shall consider briefly these points.

It has been stated time and again as a fundamental rule that in an indictment all the essential elements of the offense must be averred with sufficient clearness and particularity to enable the accused to understand the nature of the charge against him and enable him intelligently to prepare to meet it, and to plead the result, whether conviction or acquittal, as his protection against another prosecution for the same offense. But the degree of particularity requisite to accomplish these purposes is all that is required. As we said in *Beard v. United States*, 65 App. D. C. 231, 234, 82 F. 2d 837, 840:

R. S. Sec. 1025^a was enacted for the purpose of preventing miscarriage of justice through the application of technical rules in relation to matters of form in indictments, and it is now universally held that the sufficiency of a criminal pleading is to be determined by practical, rather than technical, considerations. Or, as the Supreme Court said, the rigor of the old common-law rules has yielded in modern practice to the general principle that formal defects not prejudicial will be disregarded. *Hagner v. United States*, 285 U. S. 427, 52 S. Ct. 417, 76 L. Ed. 861.

In *Nash v. United States*, 229 U. S. 373, 378, it was held that no overt acts need be charged in an indictment under the Sherman Act, and the cases under the act show that the indictments usually set out the organization of defendants, the extent of their control over the trade, their relations with each other, and the means whereby they conspired to perpetrate the restraint.⁹ The indictment at hand contains these averments. It charges that all the defendants have engaged in a combination and conspiracy in restraint of trade. It sets out the place of the conspiracy and the plans of the conspirators and the means taken to make them effective. The restraint was to be imposed on Group Health, on physicians, and on Washington hospitals, and it is

specifically stated that the conspiracy was to prevent doctors of Group Health from treating and operating on patients in the hospitals within the District of Columbia. The preamble to the resolution adopted by District Society, to which we have already referred, declares the society's apparent power of hindering Group Health if it can prevent patients of physicians in the employ of Group Health being received in the hospitals, and the indictment charges the subsequent circulation among the hospitals of the white list as the means to this end. This is a sufficient charge of a conspiracy to restrain the business of Group Health, the doctors, and the hospitals.

The "background" of the conspiracy as described in the indictment cannot, under any circumstances we can think of, be considered as prejudicial, and its relevancy, we think, is established by the opinion of the Supreme Court in *Chicago Board of Trade v. United States*, 246 U. S. at p. 238.

Allegations as to the power of the medical organizations are not irrelevant. They give to the conspiracy a significance in regard to restraining the practice of medicine, which it might not otherwise have, and are similar to allegations, in other indictments, of the control over a large amount of a particular trade.

The point that Group Health is not sufficiently described is answered in the paragraph of the indictment which sets out its incorporation, its purpose, its character, its activities, and its relationship to its members.

The alleged variance between the risk sharing plans described in the "background," which it is charged the American Medical Association habitually opposed, and the plan of Group Health, seems to us immaterial. The obvious purpose of the indictment is to charge that all risk sharing plans have been opposed and that the present restraint is merely another attack.

We think it was unnecessary to set out any more detailed facts as to the contents of the Principles of Medical Ethics and the operations of committees and society meetings. Cf. *Mercer v. U. S.*, 61 F. 2d 97, 98-9. It is enough to charge the conspiracy and the means used to effect the unlawful restraints. Overt acts are unnecessary. *Nash v. U. S.*, *supra*.

There is a sufficient allegation of dates. The indictment, it is true, states the beginning of the conspiracy shortly prior to the incorporation of Group Health, but it also shows that it continued to the date of the presentation of the indictment. That is enough.

The final point is that there is no definite charge against the individual defendants. The indictment in the opening paragraph names the associations and persons made defendants. The individuals are stated as the persons "who will be referred to hereinafter as 'individual defendants,'" and they are thereafter described in the succeeding paragraphs as members or officers in the societies and members in or officers of the hospitals or members on the staffs of the hospitals; and it is clear that their activities in the conspiracy are charged as done in their several stated capacities. All are charged with participation in the formation and furtherance of the conspiracy.

In view of the foregoing, we have no doubt that, reading the indictment as a whole, it states a case under sec. 3 of the Sherman Act.

Reversed and Remanded.

		Supplying of Oxygen Tents by State	979		
		Liability for Injuries or Diseases of Employees	979		
		B. Particular Types of Private Hospitals	979		
		Maternity Hospitals	979		

V. RIGHTS AND DUTIES OF PRACTITIONERS

A. Rights and Privileges

INSURING PAYMENT OF MEDICAL BILLS.—*Lien for Physicians.*—Proposals failed of enactment in five states³⁵⁶ to grant to physicians treating persons injured through the negligence of others liens on all rights of action, claims, judgments, compromises or settlements accruing to the injured persons by reason of their injuries. Two bills were rejected in New Jersey³⁵⁷ to amend the law granting such a lien to a licensed physician. A bill which, if enacted, would have had the effect of giving an attending physician a broad lien on all the property, both real and personal, of the person or persons employing him was rejected in South Dakota.³⁵⁸

Priority of Physicians' Claims Against Assets of Insolvent Decedent.—A bill died in Delaware³⁵⁹ which proposed that in the distribution of the assets of an insolvent decedent funeral expenses and reasonable bills for medicine and medical attendance during the last sickness and for nursing should be paid before any other claims against the estate.

Motor Vehicle Accident Compensation.—Bills failed of enactment in New York³⁶⁰ and North Carolina³⁶¹ which, in effect, proposed to require motor vehicle owners in applying for an automobile license either to furnish a bond or an insurance policy or to pay a sum in addition to the registration fee required by law for the purpose of establishing a fund with which to pay the hospitalization and medical expenses of persons injured in motor vehicle accidents.

EQUAL RIGHTS FOR PRACTITIONERS OF ALL KINDS.—*Right to Practice in Hospitals.*—Bills were killed in eight states³⁶² to require all governmental hospitals and hospitals supported in whole or in part by public funds or exempt from taxation to permit all practitioners of the healing art to practice within their confines. Three of these bills³⁶³ proposed also to impose this requirement on all hospitals whether or not they received any public moneys or were exempt from taxation. An Arizona bill³⁶⁴ which would have required governmental hospitals to permit osteopaths to practice therein on the same terms and under the same conditions as doctors of medicine was killed. The Washington senate also rejected a similar proposal³⁶⁵ to make it unlawful for any hospital organized as a charitable institution to refuse to any licensed physician and surgeon the use of facilities therein or the right to attend patients therein, for the direct or indirect reason that a particular physician and surgeon contracts to give medical service in consideration of payment of periodical premiums or dues or because of any physician's membership or nonmembership in any society or other lawful organization.

An unsuccessful Maine bill³⁶⁶ proposed that all tax-exempt hospitals or hospitals receiving public funds must permit osteopaths licensed to practice obstetrics and surgery to practice therein and must furnish laboratory service to outpatients of such practitioners. Another Maine bill was also killed³⁶⁷ which proposed that such hospitals must furnish laboratory services to such practitioners. A defeated Wisconsin bill³⁶⁸ proposed that no hospital supported in whole or in part by public funds or exempt from taxation should discriminate against any physician whose license to practice had been revoked and subsequently restored.

356. Del. S. 253; Ill. S. 52 (this bill was enacted but as enacted the lien is given to hospitals only); N. Y. S. 337, A. 413; Ore. S. 353; S. C. S. 325.

357. N. J. S. 209, S. 210.

358. S. D. S. 25.

359. Del. S. 225.

360. N. Y. A. 1280.

361. N. C. S. 185.

362. Ark. S. 293; Calif. A. 2809; Conn. H. 1025; Mich. S. 424; Minn. H. 1484; N. Y. A. 1137; N. D. H. 170; Okla. H. 103.

363. Calif. A. 2809; Minn. H. 1484; Okla. H. 103.

364. Ariz. H. 115.

365. Wash. S. 159.

366. Me. H. 1706.

367. Me. H. 2238.

368. Wis. A. 543.

Right to Treat Workmen's Compensation Cases.—Proposals failed in California,³⁶⁹ Oregon,³⁷⁰ Washington³⁷¹ and Wisconsin³⁷² which, if enacted, would have permitted an injured workman to have his industrial injury treated by any person licensed to practice any of the healing arts at the expense of the state or at the expense of the employer, according to the particular compensation law. An Arizona bill,³⁷³ which was killed, proposed in effect to confer on osteopaths the right to treat compensation cases. Proposals to confer similar rights on chiropractors were killed in Minnesota³⁷⁴ and Wisconsin.³⁷⁵

Right to Treat Relief Cases or to Participate in Public Health Programs.—Laws were enacted in South Dakota³⁷⁶ and Tennessee³⁷⁷ which provide, in effect, that in expending public funds for medical care no distinction is to be drawn between the legally authorized branches of healing. The South Dakota law specifically gives each relief client the right to select a practitioner of his own choice, regardless of school of practice. However, the South Dakota law does provide that it is not to affect the state board of health in the administration of the program relating to services for crippled children.

Bills were killed in Missouri,³⁷⁸ New York³⁷⁹ and North Dakota³⁸⁰ which proposed, in effect, that in the providing of medical assistance to indigent persons equal rights and privileges had to be given to licensed practitioners of every school of medicine or healing recognized by the laws of the state. Somewhat similar bills were killed in Arizona,³⁸¹ Massachusetts,³⁸² Missouri,³⁸³ Oklahoma³⁸⁴ and Rhode Island³⁸⁵ which provided that in public health work and in the distributing of medical care to the indigent all doctors of medicine and osteopaths must be accorded equal rights and privileges. A bill was killed in Arkansas³⁸⁶ which proposed that whenever any public funds were to be used to pay any part of the medical or hospital fees of any person employed on any project under the supervision and control of the state or federal government, all licensed physicians and surgeons in the state and all regularly operated hospitals had to be given an equal right to attend and/or hospitalize such persons.

VENEREAL PROPHYLACTICS.—A law was enacted in Washington³⁸⁷ which provided for the sale, distribution, or other distribution, except by prescription, of any device, medical preparation or compound which is or may be used, designed, intended, or which has or may have special utility, for the prevention and/or treatment of venereal diseases.

Similar bills were killed in four other states.³⁸⁸

PRIVILEGED COMMUNICATIONS.—The New Mexico privileged communication law was so amended this year³⁸⁹ as to provide that a licensed physician or nurse cannot be examined without the consent of the patient as to any communication made by the patient with reference to any real or supposed venereal or loathsome disease or any knowledge concerning such disease. The new law further provides that no physician or nurse

employed by a workmen's compensation claimant can be required to divulge any information obtained while treating the claimant except where the treatment is at the expense of the employer.

Unsuccessful attempts were made in three states³⁹⁰ to provide that in any civil or criminal cause a licensed physician should not be allowed or compelled to disclose, except with the patient's consent, any information acquired in attending a patient which was necessary to enable the physician to prescribe or act for the patient. A similar bill was introduced in Alabama³⁹¹ and may be acted on when the legislature convenes again in June 1940.

Unsuccessful attempts were made in Ohio and Utah to amend the laws³⁹² prohibiting a physician from testifying concerning a communication made to him by his patient in that relation except by the express consent of the patient.

EXPERT WITNESSES.—Bills were killed in five states³⁹³ proposing that whenever in any civil or criminal proceeding issues arise on which the court deems expert evidence desirable, it may appoint one or more experts, not exceeding three on any issue, to testify at the trial, and the fact that such experts have been appointed by the court was to have been made known to the jury.³⁹⁴ The Pennsylvania House rejected a proposal³⁹⁵ that a written report or a finding of facts prepared by an expert not a party to a cause nor an employee of a party nor financially interested in the result of the controversy, containing the conclusions resulting wholly or partly from written information by the cooperation of several persons acting for a common purpose, should, as far as the same might be relevant, be admissible when testified to by the person or one of the persons making such report or finding without calling as witnesses the persons furnishing the information and without producing the books or other writings on which the report or finding was based, if in the opinion of the court no substantial injustice would have been done to the opposing party.

LIMITATION ON MALPRACTICE ACTIONS.—A new Missouri law³⁹⁶ provides that a licensed physician or the owner or operator of any private sanatorium or hospital shall not be liable in damages for the restraint of any insane person or persons of feeble or disordered mind by reason of having in good faith furnished care, treatment or attention to such persons.

An unsuccessful attempt was made in Indiana³⁹⁷ to provide that all actions against physicians, dentists, hospitals or sanatoriums for malpractice, error, mistake or failure to cure should be commenced within two years after the cause of action accrues and that a cause of action would be deemed to have accrued on the date of the act or neglect complained of. Two bills failed of enactment in Arkansas³⁹⁸ which proposed to require malpractice actions to be instituted within three years after the accrual of the cause of action. A cause of action, however, was not to be deemed to have accrued until the date it is discovered by the patient.

RIGHT TO COMPOUND AND DISPENSE PRESCRIPTIONS.—A bill died in Florida³⁹⁹ proposing to authorize every licensed physician to compound and fill prescriptions written by him in his practice from a drugstore or apothecary owned and operated by him.

RIGHT TO EXTRACT TEETH.—A new Arkansas law⁴⁰⁰ amends the dental practice act so as to provide

399. Fla. H. 234.

400. Ark. Acts, 1939, Act No. 157.

that nothing therein "shall prohibit or prevent any licensed physician from extracting teeth in an emergency when he shall deem it advisable and when a licensed dentist is not reasonably available."

EXEMPTION FROM OCCUPATIONAL TAX.—A bill was killed in Arkansas ⁴⁰¹ proposing to exempt from the payment of any privilege or occupational tax levied by any city or town which does not maintain a free medical clinic any physician whose services are largely given to the care of the indigent sick.

RIGHT OF ALLEGED INSANE PERSON TO EXAMINATION BY PHYSICIAN OF OWN CHOICE.—An unsuccessful attempt was made in Massachusetts ⁴⁰² to provide that when a person under complaint or indictment for crime is committed to a hospital for the insane, the defendant shall have the right to be examined as to his mental condition by two physicians selected by him and that all reasonable expenses incurred by such examination should be paid as in the case of other court expenses.

B. Duties and Liabilities

OCCUPATIONAL TAXES.—The Revenue Act of 1939 of North Carolina ⁴⁰³ imposes an annual tax of \$25 on practicing physicians, osteopaths, chiropractors, chiropodists, dentists, optometrists, opticians and any other person practicing "any professional art of healing for a fee or reward."

An unsuccessful attempt was made in Massachusetts ⁴⁰⁴ to impose an annual occupational tax of \$5 on all persons practicing any profession. A bill was killed in Washington ⁴⁰⁵ to impose an additional annual license fee of \$5 on physicians, \$3 on drugless healers and \$3 on midwives. The legislature of Florida killed a bill ⁴⁰⁶ to amend the law imposing an annual state license tax on practitioners of any profession so as to permit counties and incorporated cities and towns each to levy an additional license tax of 50 per cent of the state license tax.

GROSS INCOME OR RECEIPT TAX.—Unsuccessful attempts were made in five states ⁴⁰⁷ to levy a tax of varying percentages on the gross income of physicians, dentists and other licensed practitioners of the healing art.

REPORTS OF WOUNDS, DISEASES AND DEFECTS.—A new Alabama law ⁴⁰⁸ requires a physician diagnosing or treating a case of syphilis, gonorrhea, chancroid, venereal lymphogranuloma or granuloma venereum to report the facts immediately to the county health officer.

A similar bill failed in New Jersey.⁴⁰⁹

A new Massachusetts law ⁴¹⁰ requires a physician in attendance at the birth of a child born with visible congenital deformities or birth injuries to report within thirty days after birth to the state department of public health and the city or town clerk of the place where the birth occurred.

A new Maryland law ⁴¹¹ requires a physician, pharmacist, dentist, hospital or nurse treating any person in Montgomery County for an injury which was caused by or shows evidence of having been caused by an automobile accident or by a lethal weapon to report the facts as soon as practicable to the county police.

A new New York law ⁴¹² requires a physician treating a patient with cancer or other malignant tumor to report the facts to the appropriate health officer.

A Montana law ⁴¹³ requires physicians treating a person suffering from a disease contracted from employment to report the facts to the state board of health. Another Montana law ⁴¹⁴ requires physicians and hospitals on the request of the Division of Industrial Hygiene to report details concerning instances of occupational diseases treated.

An unsuccessful attempt was made in Indiana ⁴¹⁵ to require every physician within twenty-four hours after first learning of the existence of an occupational disease to report the facts to the state board of health.

Proposals were rejected in Pennsylvania to require physicians to report stated defects or diseases to the appropriate health authorities. One bill ⁴¹⁶ proposed to require such a report with respect to a patient in whom is found sex abnormality, sex perversion or sex criminal tendencies. Another bill ⁴¹⁷ proposed to require a physician to report to designated health authorities the name of any patient suffering from or affected with any disease which is communicable, infectious or contagious. Bills were killed in Pennsylvania ⁴¹⁸ and Texas ⁴¹⁹ to require every physician to notify in writing the appropriate local health officer of every case of any form of tuberculosis which comes under his professional observation.

INSTILLING PROPHYLAXIS INTO INFANTS' EYES.—A new South Carolina law ⁴²⁰ requires every physician, midwife, nurse or other person attending the delivery at birth of a child to instill, or have instilled, into the eyes of the baby within one hour after birth a 1 per cent solution of silver nitrate, or some equally effective prophylactic approved by the state department of public health, for the prevention of blindness from ophthalmia neonatorum.

Similar bills were considered and killed in California ⁴²¹ and Florida,⁴²² the Florida bill being vetoed by the governor.

DESIGNATION OF SCHOOL OF PRACTICE.—A new West Virginia law makes it unlawful for any person to use the prefix "Doctor" or "Dr." in connection with his name in any letter, business card, advertisement, sign or public display of any nature without affixing thereto suitable words or letters designating the degree which he holds.⁴²³

A somewhat similar bill ⁴²⁴ was killed in New Mexico.

The Oregon law requiring a person using the title "Doctor" in connection with the practice of the healing art to add after his name a designation of his school of practice was so amended this year ⁴²⁵ as to require a person using the expression "clinic, institute, specialist or any other assumed or artificial name or title" in connection with the practice of the healing art to add after any such assumed or artificial name a designation of his school of practice. No person may use any designation or artificial or assumed name except a person licensed to practice in Oregon.

SEROLOGIC TESTS OF PREGNANT WOMEN.—A detailed discussion of the legislation considered this year to require physicians attending pregnant women to take

samples of their blood and to make or cause to be made serologic tests for syphilis will be found on page 878.

PROHIBITION OF OPERATION TO IMPEDE IN IDENTIFICATION.—Bills were considered and killed in New York⁴²⁶ to prohibit the performance of an operation, the purpose or effect of which is to change or alter the skin or tissues of the fingers or thumbs so as to alter such person's finger patterns or fingerprints, and to prohibit also the performing of any operation of plastic surgery on a known criminal, the purpose or effect of which is to alter his personal appearance and make identification and apprehension difficult. These bills also proposed to require a physician to report immediately to appropriate police officials all requests for operations which seem to come within the provisions of the bill.

LIMITATION ON RIGHT TO DISPENSE.—A bill failed of enactment in Wisconsin⁴²⁷ proposing so to amend the pharmacy practice act as to provide that its provisions should not interfere with the dispensing of drugs by physicians in an emergency, provided only such drugs shall be kept in stock by a physician as are necessary for emergency use.

ANNUAL RENEWAL OF LICENSES.—A proposal to require all persons licensed to practice medicine, osteopathy or chiropractic to renew their licenses annually with their respective boards of examiners and to condition renewal on the presentation of evidence that the applicant in the preceding year had attended recognized classes or clinics for the purpose of pursuing postgraduate study of subject or subjects pertinent to his system of healing for not less than ten class hours of fifty minutes each during the year was rejected in Michigan.⁴²⁸

LIMITATION ON FEE CHARGED.—A bill was killed in Oklahoma⁴²⁹ to prohibit a licensed practitioner of the healing art, in making professional calls away from his office, to charge or collect more than his regular fee for each call plus fifty cents per mile for each mile actually and necessarily traveled in going from his office to the place where he attended the patient.

BLOOD TESTS ON PHYSICIANS.—An unsuccessful attempt was made in Indiana⁴³⁰ to require every physician, dentist and nurse, at least once every two years, to cause to be submitted to an approved laboratory for a standard serologic test for syphilis a sample of his or her blood. If such test showed that the practitioner was infected with syphilis the license of that practitioner was automatically to be suspended and remain suspended so long as the disease was in a communicable stage.

WRITTEN DIAGNOSIS TO BE GIVEN PATIENT PRIOR TO OPERATION.—Bills were rejected in two states⁴³¹ which proposed to require a physician either before performing an operation or after removing an organ or limb to deliver a written explanation as to the nature of the operation performed or to be performed and the reason that such an operation was necessary. One of these bills⁴³² proposed to require the physician to deliver one copy of the diagnosis referred to to the patient and one copy to the state board of health, which was to preserve it as a permanent public record. One of the bills⁴³³ proposed, in addition, to require a hospital wherein a limb or organ of a patient had been removed to preserve the limb or organ until such time, not exceeding six weeks after the operation, as it should be made known to the hospital whether or not the patient wished to view the limb or organ.

SECRET REMEDIES TO BE REVEALED TO STATE BOARD OF HEALTH.—A bill was withdrawn by its sponsor in Arkansas⁴³⁴ which proposed to require any hospital, physician or person engaged in any of the healing arts who claims to possess a secret remedy which will relieve human suffering to deliver such secret to the state board of health for the benefit of the people of the state.

VI. LEGISLATION RELATING TO ALLIED PROFESSIONS AND SUNDRY VOCATIONS

DENTISTRY.—Laws amending or supplementing existing dental practice acts were adopted in Arizona,⁴³⁵ Arkansas,⁴³⁶ California,⁴³⁷ Delaware,⁴³⁸ Illinois,⁴³⁹ Kansas,⁴⁴⁰ Maine,⁴⁴¹ Maryland,⁴⁴² Michigan,⁴⁴³ New Hampshire,⁴⁴⁴ New Jersey,⁴⁴⁵ New Mexico,⁴⁴⁶ Oregon,⁴⁴⁷ Rhode Island⁴⁴⁸ and Wisconsin.⁴⁴⁹ The new Arizona, Michigan and Rhode Island laws among other things, impose certain prohibitions against advertising on the part of licentiates. Generally, the laws follow the language used in an amendment to the Oregon dental practice act adopted in 1933, which the Supreme Court of the United States has held valid in *Semler v. Oregon State Board of Dental Examiners*, 55 S. Ct. 570. The provisions in question either authorize the revocation of a license or impose a penalty on a licentiate guilty of "advertising professional superiority or the performance of professional services in a superior manner; advertising prices for professional service; advertising by means of large display, glaring light signs, or containing as a part thereof the representation of a tooth, teeth, bridgework or any parts of the human head; employing or making use of advertising solicitors or free publicity agent; or advertising any free dental work or free examination; or advertising to guarantee any dental services, or to perform any dental operation painlessly."

The new Michigan law is of particular interest in that it also forbids a dentist from announcing or holding himself out to the public as limiting his practice to, or as being especially qualified in, or as giving special attention to, any branch of dentistry, without first having obtained a license therefor from the board of dental examiners. Before an applicant can obtain such a license he must prove to the board that he has had a minimum of one year of postgraduate work in any one of the several recognized branches of dentistry in an approved college or university and has complied with any additional requirements that the board might impose. The license that the board issues in such cases authorizes the dentist to hold himself out or to announce to the public that he is especially qualified to, or limits his practice to, or gives especial attention to such recognized branch of the dental profession as the license states.

The new Maryland law makes it a misdemeanor for any person, corporation, partnership or dental laboratory to solicit or advertise by mail, card, newspaper, pamphlet, radio or otherwise, to the general public to construct, produce or repair prosthetic dentures, bridges, plates, appliances or other appliances to be used or worn as substitutes for natural teeth.

Legislation specifically prohibiting unlicensed individuals from managing, operating, owning or conduct-

ing a place where dental operations are performed was enacted in Illinois⁴⁵⁰ and Wisconsin.⁴⁵¹

A new Wyoming law⁴⁵² requires one member of the state board of health to be a licensed dentist.

Unsuccessful attempts were made in eleven states to amend existing dental practice acts.⁴⁵³

A bill, which died in Illinois,⁴⁵⁴ proposed a procedure whereby a person might obtain a license to engage in dental laboratory services and to prohibit unlicensed persons from engaging in such services. The bill proposed, however, that its provisions should not apply to licensed dentists and to persons who render dental laboratory services exclusively for not more than one dentist. A far reaching proposal was killed in California⁴⁵⁵ which proposed to create the dental corporation of California, to consist of all licensed dentists and licensed dental hygienists in the state and to be governed by a state dental board, whose members were to be selected by members of the corporation. Members of the existing board of state dental examiners were to be the first state dental board, but as their terms expired they were to be replaced by persons selected by the corporation. This state dental board was to exercise all the rights and assume all the duties now exercised by the board of dental examiners.

NURSING.—New nursing practice acts were adopted in California,⁴⁵⁶ Connecticut⁴⁵⁷ and Missouri.⁴⁵⁸ The new California law⁴⁵⁹ defines the practice of nursing as "the performing of professional services requiring technical skill and specific knowledge based on the principles of scientific medicine, such as are acquired by means of a prescribed course in an accredited school of nursing . . . and practiced in conjunction with curative or preventive medicine as prescribed by a licensed physician and the application of such nursing procedures as involve understanding cause and effect in order to safeguard life and health of a patient and others." The law then prohibits a person from practicing nursing as just defined unless licensed by the board of nurse examiners. The new Connecticut law contains somewhat similar provisions. It defines the practice of nursing as "(a) The performing, for compensation and under the direction of a licensed physician, of any professional service requiring special education, knowledge and skill in nursing care of those mentally or physically ill and in the prevention of illness; or (b) the performing, for compensation and under the direction of a licensed physician, of any of the simpler procedures required in nursing care of the sick, not involving the specialized education, knowledge and skill specified in subsection (a)." The law then prohibits any person from practicing nursing as just defined unless registered or certified in accordance with the terms of the act.

Existing nursing practice acts were amended in Alabama,⁴⁶⁰ Illinois,⁴⁶¹ Maine,⁴⁶² Michigan,⁴⁶³ New Hampshire,⁴⁶⁴ North Dakota,⁴⁶⁵ Oklahoma,⁴⁶⁶ Ten-

nessee⁴⁶⁷ and Vermont.⁴⁶⁸ Of particular interest is a provision in the new Illinois law which requires applicants for certificates as registered nurses to be citizens of the United States.

Unsuccessful attempts were made in eleven states to amend existing nursing practice acts.⁴⁶⁹

MEDICAL TECHNICIANS.—Unsuccessful attempts were made in Florida⁴⁷⁰ to enact a so-called medical technicians practice act and to create a board of examiners to examine and license persons to practice as medical technicians. The bills proposed to define "a medical technician" as a "person who is engaged in the practice of standardized or experimental technical procedures, the results of which are interpreted by the physician in the diagnosis of disease." The bills proposed that the provisions of the act should not apply to an office assistant or nurse who, in addition to his or her routine duties, performed such laboratory procedures as ordinary blood counts, urinalyses and basal metabolic tests whose results are used only by the employer-physician in his private practice of medicine and who assumes responsibility for the work so performed.

PHARMACY.—A new pharmacy practice act was enacted this year in New York.⁴⁷¹ Existing pharmacy practice acts were amended or supplemented by laws enacted in nineteen other states.⁴⁷² The new laws as a rule are not of sufficient interest to warrant a detailed discussion here. Among other things, one of the new Maine laws⁴⁷³ makes it unlawful for any person to distribute at retail any veronal or barbitol or any other salts, derivatives or compounds of barbituric acid, or any registered, trade-marked or copyrighted preparation registered in the United States Patent Office containing the above substances, except on the written order or prescription of a licensed physician, dentist or veterinarian. The prior law permitted such drugs to be distributed at retail if dispensed by a pharmacist. The prior laws did not limit the distribution of any registered, trade-marked or copyrighted preparation registered in the United States Patent Office containing the drugs referred to unless it contained more than 40 grains (2.6 Gm.) to the avoirdupois fluid ounce (30 cc.). The new Massachusetts law⁴⁷⁴ vests in the board of registration in pharmacy discretionary power in granting permits to stores to transact a retail drug business. Under the prior law the board had no discretion in the matter and was forced to grant a permit with respect to an application made in a proper manner. The new Montana law⁴⁷⁵ authorizes the state board of pharmacy to license stores other than pharmacies wherein may be sold ordinary household or medicinal drugs prepared in sealed packages or bottled by manufacturers. The new Washington law⁴⁷⁶ requires every proprietor or manager of a pharmacy or drug store to keep in his place of business a suitable book or file of

the original of every prescription compounded or dispensed therein, numbering, dating and filing them in the order in which they were compounded or dispensed, and preserving them for not less than five years. The new law also requires that on the container of a prescription there shall be fixed a label bearing the name and address of the pharmacy wherein compounded, the corresponding serial number of the prescription, the name of the prescriber, his directions, the name of the patient and the date and initials of the registered pharmacist who compounded the prescription.

Various bills proposing to amend existing pharmacy practice acts were killed in twenty-three states.⁴⁷⁷

CHIROPODY.—Bills to enact separate chiropody or podiatry practice acts and to provide for the examining and licensing of such practitioners by an independent board of examiners were considered in three states.⁴⁷⁸ Only one state, New Mexico, enacted such a law.⁴⁷⁹ The definition of chiropody in the New Mexico law seems extremely broad. Chiropody is defined as "The diagnosis and the medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human foot excepting amputation of the foot or toes or the administration of an anesthetic other than local."

The Alabama medical practice act was so amended this year⁴⁸⁰ as to authorize the state board of medical examiners to license persons to practice chiropody. Such practitioners, however, are authorized to diagnose only local ailments of the human foot and to treat such ailments only locally, extending treatment no deeper than the true skin and using only local anesthetics in connection with such treatment. Applicants for such a license must possess such qualifications and submit to such examinations as in the judgment of the board of medical examiners are necessary for the protection of the public health. Such examinations must embrace the anatomy and physiology of the foot; the diagnosis and treatment of diseases and ailments of the foot, asepsis, antisepsis, therapeutics and clinical chiropody.

Amendments to existing chiropody practice acts were adopted in Connecticut,⁴⁸¹ Delaware,⁴⁸² Florida,⁴⁸³ Illinois,⁴⁸⁴ Michigan,⁴⁸⁵ Minnesota,⁴⁸⁶ Montana⁴⁸⁷ and Texas.⁴⁸⁸ One of the new Illinois laws⁴⁸⁹ requires all applicants for such licenses to be citizens of the United States. The laws adopted in Michigan, Montana and Texas, among other things, seem to extend the scope of a license to practice chiropody. The new Michigan law seems to permit such practitioners to treat ailments of the human foot by physiotherapy. The new Montana law states that chiropody is "the diagnosis, medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human foot" but prohibits chiropodists from amputating the human foot or toes or from administering any anesthetic other than local. The new Texas law permits such licentiates to

treat ailments of the human foot by any system or method, either medical, surgical, mechanical, manipulative or massage, physiotherapy, mechanotherapy, electrical appliance or other system or method but prohibits a chiropodist from amputating the human foot or toe or from administering any anesthetic other than local. The new Delaware law⁴⁹⁰ purports to raise the educational qualifications of chiropody applicants by requiring them to present proof that they have obtained a doctor's degree in chiropody after graduating from an accredited college or university, which requires as a prerequisite to graduation a four year course of instruction in chiropody, consisting of at least eight months of instruction a year and a total of at least 3,980 hours of instruction for the four year course.

A new California law⁴⁹¹ requires chiropody applicants to have completed a one year resident course of work of college grade in a school approved by the board of medical examiners before commencing the resident course of study in chiropody.

An unsuccessful attempt was made to repeal the chiropody practice act of Tennessee.⁴⁹²

Unsuccessful attempts were made in seven states to amend existing laws regulating the practice of chiropody.⁴⁹³

OPTOMETRY.—New optometry practice acts were enacted this year in Florida⁴⁹⁴ and Wyoming.⁴⁹⁵ The new Florida law defines optometry as "the diagnosis of the human eye and its appendages, and the employment of any objective or subjective means or methods for the purpose of determining the refractive powers of the human eyes, or any visual, muscular, neurological or anatomic anomalies of the human eyes and their appendages, and the prescribing and employment of lenses, prisms, frames, mountings, orthoptic exercises, light frequencies and any other means or methods for the correction, remedy, or relief of any insufficiencies or abnormal conditions of the human eyes and their appendages." The law also requires courts and governmental agencies to accept the testimony and services of optometrists on the same basis, and on a parity "with any other person or persons authorized by law to render similar professional service." The new Wyoming law defines optometry as "the employment of any means other than the use of drugs for the measurement of the powers or range of human vision or the determination of the accommodative and refractive status of the human eye or the scope of its functions in general or the adaptation of lenses or frames for the aid thereof." The new law specifically prohibits an optometrist from using the title "oculist" or "ophthalmologist" or any other word or abbreviation indicating that he is engaged in the treatment of diseases of or injuries to the human eye, or possesses the right to use drugs or medicine in any form for the treatment or examination of the human eye.

Amendments to existing optometry practice acts were adopted in Arkansas,⁴⁹⁶ California,⁴⁹⁷ Connecticut,⁴⁹⁸ Delaware,⁴⁹⁹ Illinois,⁵⁰⁰ Kansas,⁵⁰¹ Maine,⁵⁰²

502. Me. Public Laws, 1939, c. 294.

Montana,⁵⁰³ Nevada,⁵⁰⁴ New Hampshire,⁵⁰⁵ New Mexico,⁵⁰⁶ New York,⁵⁰⁷ Tennessee⁵⁰⁸ and Texas.⁵⁰⁹ As a general rule, the amendments are not of sufficient interest to warrant discussion here. However, the new Illinois law⁵¹⁰ and one of the laws adopted in New Hampshire⁵¹¹ require applicants for licenses to be citizens of the United States. The new laws adopted in Montana and Tennessee, among other things, prohibit optometrists from advertising the prices for which they will render services or supply materials. The new New Mexico law broadens the prior definition of optometry by defining it as "the employment of an [sic] subjective or objective means or methods, other than the use of drugs or surgery, for the purpose of determining the refractive condition of the human eye or any muscular or visual anomalies thereof; or the employment, adapting or prescribing of lenses, prisms, or other optical appliances, or other means, modalities or methods, not including drugs, medicines or surgery for the correction or relief of disturbances in and anomalies of the human visual system and its supportive functions."

The new Arkansas law declares the practice of optometry to be a learned profession [sic] and states that the same rights and powers attach thereto as to the other learned professions. The law defines optometry as "the employment of any method or means other than the use of drugs, medicine or surgery, for the analysis of any optical defect, deficiency, or deformity, visual or muscular anomaly of the visual functions, or the use of scientific instruments to train the visual system."

Unsuccessful attempts were made to amend the optometry practice act in twenty-three states.⁵¹²

OPTICIANS—OPHTHALMIC DISPENSING.—A new California law⁵¹³ provides a practice act for dispensing opticians. The law requires registration with the board of medical examiners of individuals and firms filling prescriptions of physicians and surgeons licensed by the board of medical examiners for ophthalmic lenses and kindred products, and, as incidental to the filling of such prescriptions, taking facial measurements and fitting and adjusting lenses or frames. The law is not to affect any licensed optometrist or physician and surgeon but the exemption is not to apply to any optometrist or physician exclusively engaged in the business of filling prescriptions for physicians and surgeons.

Bills were killed in California,⁵¹⁴ proposing a practice act for persons engaged in optical dispensing and limiting optical dispensing to persons licensed to do so by the board of optometrical examiners.

Optician practice acts were considered and killed in Massachusetts,⁵¹⁵ Pennsylvania⁵¹⁶ and New York⁵¹⁷ which proposed to establish independent boards of optician examiners.

VII. BILLS AFFECTING HOSPITALS

A. Hospitals Generally

CONTRACTS FOR HOSPITALIZATION; HOSPITALIZATION INSURANCE.—Legislation to authorize the formation of corporations to provide on a "nonprofit basis," "hospital care" to their members and subscribers have been discussed in this survey on page 876.

LIENS FOR HOSPITALS.—Laws were enacted in Illinois,⁵¹⁸ Kansas⁵¹⁹ and Rhode Island⁵²⁰ granting liens to all hospitals treating persons injured through the negligence of others on all claims, rights of action, settlements, judgments or compromises accruing to the injured persons because of their injuries.

Similar bills were killed in six other states.⁵²¹

The New York law granting hospital liens of this type was amended this year⁵²² so as to provide that the fee for filing a claim of lien in the counties comprising the city of New York shall be 50 cents and that the fee for filing a discharge of lien in those counties shall be \$1.

Unsuccessful attempts were made to amend the New York hospital lien act in other particulars.⁵²³ Attempts likewise failed in three other states⁵²⁴ to amend existing hospital lien acts.

PAYMENT BY STATE FOR HOSPITAL CARE.—Unsuccessful attempts were made in four states⁵²⁵ to provide a procedure whereby hospitals might be reimbursed by the state for care and treatment rendered indigents injured in motor vehicle accidents.

Proposals were killed in New York⁵²⁶ and North Carolina⁵²⁷ to require applicants for automobile licenses to pay stated additional fees to establish a fund which was to pay the hospitalization expenses of persons injured in motor vehicle accidents.

FACILITIES AVAILABLE TO CULTISTS.—Proposals to require all private hospitals, or certain types of private hospitals, to permit any licensed practitioner of the healing art to treat patients within their confines has been discussed in this survey on page 972.

LICENSING OF ALL PRIVATE HOSPITALS.—Bills to require the annual licensing of all private hospitals by specified state agencies were killed in five states.⁵²⁸

HOSPITAL EMPLOYEES.—Bills to limit the hours of employment in hospitals of nurses to not more than eight hours a day were killed in three states.⁵²⁹

REPORTING OF WOUNDS, INJURIES AND DEFECTS.—Legislation proposing to require hospitals to report the status of wounds, injuries and defects, has been considered in this survey on page 974.

PAYMENT OF SALARIES TO INTERNS.—An unsuccessful attempt was made in Pennsylvania⁵³⁰ to require all hospitals receiving appropriations from the commonwealth to pay each intern an annual salary of not less than \$1,000.

all hospital employees).

530. Pa. H. 682.

HOSPITAL RECORDS.—A bill was killed in New York⁵³¹ to make hospital records or copies thereof, when certified by an officer in charge of the hospital, admissible as evidence in courts of record, provided only that any declarations or statements contained in said record made by an injured party of a non-medical nature or which are explanatory or descriptive of the occurrence, happening or accident in question, were not to be admissible. A California bill, which was killed,⁵³² proposed to require hospitals to keep records on file for at least three years after the patient had been discharged and to permit the patient or his representative to inspect the records and make copies thereof.

MISCELLANEOUS.—A new South Carolina law⁵³³ provides a penalty for any person who operates a radio or other musical instrument in such a manner that it disturbs any patient confined to a hospital or sanatorium. A law enacted in Massachusetts⁵³⁴ prohibits employees and persons connected with hospitals from furnishing information about personal injury cases to attorneys or their representatives.

LIABILITY OF CHARITABLE HOSPITALS FOR NEGLIGENCE OF EMPLOYEES.—The Illinois senate rejected a proposal⁵³⁵ that corporations not for pecuniary profit shall be liable for the negligence of their officers, agents and servants in the course of their authorized duties and employment.

THE PRACTICE OF MEDICINE BY HOSPITALS.—An unsuccessful Missouri bill⁵³⁶ proposed, in effect, to permit hospitals to practice medicine through the agency of physicians, osteopaths and dentists in their employ.

SUPPLYING OF OXYGEN TENTS BY STATE.—Two bills were killed in Massachusetts⁵³⁷ proposing to require the state to furnish oxygen tents to stated types of hospitals.

LIABILITY FOR INJURIES OR DISEASES OF EMPLOYEES.—An unsuccessful attempt was made to amend the Pennsylvania workmen's compensation act⁵³⁸ so as to make compensable as an occupational disease a contagious disease of any kind contracted by a person employed in or about any hospital where persons having contagious diseases are admitted for treatment. Unsuccessful attempts were made in New York⁵³⁹ to include within the workmen's compensation act employment in hospitals.

B. Particular Types of Private Hospitals

MATERNITY HOSPITALS.—A new law was adopted in Oregon⁵⁴⁰ prohibiting the operation of a maternity hospital or other place for the reception, care and treatment of women during pregnancy or within ten days after delivery unless licensed by the state board of health.

Similar bills were killed in North Dakota⁵⁴¹ and Utah.⁵⁴²

The Illinois law regulating the operation of maternity hospitals was amended this year⁵⁴³ in several particulars. Most important is a requirement that such a hospital to be licensed or to retain licensure must possess equipment necessary for its purpose and must be safe and sanitary. No such hospital is permitted to place a child for adoption or care unless it is licensed as a child welfare agency.

An unsuccessful attempt was made so to amend the Colorado law⁵⁴⁴ relating to the supervision and licensing of child welfare agencies, boarding homes and maternity hospitals.

C. Governmental Hospitals

FACILITIES AVAILABLE TO CULTISTS.—Legislative proposals to require governmental hospitals to permit any licensed practitioner of the healing art to treat patients within their confines have been discussed in this survey on page 972.

STATE HOSPITALS FOR THE TREATMENT OF TUBERCULOSIS.—A new North Carolina law⁵⁴⁵ authorizes the establishment in eastern North Carolina of a sanatorium for the treatment of persons afflicted with tuberculosis.

Bills to authorize either the establishment of a state hospital for the treatment of tuberculosis or additional hospitals for such purposes were killed in four states.⁵⁴⁶

STATE HOSPITALS FOR THE INSANE.—Unsuccessful attempts were made in two states⁵⁴⁷ to authorize the establishment and operation of additional state hospitals for the care, treatment and maintenance of insane persons. An unsuccessful attempt was made in Wisconsin⁵⁴⁸ to require the establishment of a chiropractic ward in a stated state hospital for the insane.

STATE PSYCHIATRIC OR PSYCHOPATHIC HOSPITALS OR CLINICS.—Laws were enacted in California,⁵⁴⁹ Delaware⁵⁵⁰ and Vermont⁵⁵¹ authorizing the establishment and operation of state psychiatric or psychopathic hospitals or clinics. The new California law provides for the operation in existing state institutions of units for the custodial care and treatment of defective or psychopathic delinquents of both sexes. The new Delaware law directs the board of trustees of the Delaware State Hospital at Farnhurst to establish a psychiatric observation clinic for the observation, study, psychiatric diagnosis and treatment of persons suffering from mental and nervous diseases. The new Vermont law establishes within the Department of Public Welfare a psychiatric clinical division which is to provide adequate local and traveling clinics at such places and at such times as will economically and efficiently examine (1) children under the supervision and jurisdiction of the public welfare department; (2) dependent, neglected or delinquent children against whom court proceedings have been instituted, and (3) children against whom complaints or petitions have been made to the state probation officer. Judges are authorized to commit children on the facts indicated to such clinics for examination and receive the results of the examinations and recommendations before passing sentence.

STATE CANCER HOSPITALS.—Unsuccessful attempts were made in Arkansas⁵⁵² to establish an institute for the hospitalization and treatment of persons suffering from cancer. The bills proposed that persons able to pay only a part of the expenses of necessary treatment might be admitted under such regulations as may be established by the board of trustees of the proposed institute.

STATE ORTHOPEDIC HOSPITALS.—Unsuccessful attempts were made in two states⁵⁵³ to establish hospitals for the prevention, treatment and cure of infantile paralysis. A proposal was rejected in California⁵⁵⁴ to establish a number of crippled children hospital districts to provide special care and treatment

and physical rehabilitation for physically defective and handicapped children under 18.

STATE HOSPITALS FOR THE TREATMENT OF INEBRIATES.—A new California law ⁵⁵⁵ directs the Director of Institutions, with the approval of the state board of control, to provide suitable units to be used for the isolation and rehabilitation of chronic inebriates. The law provides a procedure whereby inebriates may be committed to the state inebriate colonies by appropriate courts.

A bill in Massachusetts ⁵⁵⁶ was referred to the next session of the legislature which proposed to provide at state expense for the care and treatment of inebriates for a period of not exceeding six months each per person so treated.

STATE HOSPITALS FOR THE CARE AND TREATMENT OF INCURABLE CHILDREN.—Unsuccessful attempts were made in Florida ⁵⁵⁷ to authorize the state board of health to establish a home for the care and treatment of incurable children.

STATE HOSPITALS FOR THE TREATMENT OF BUEYER'S DISEASE.—A new Washington law ⁵⁵⁸ authorizes the establishment at Soap Lake of an institution to be known as the McKay Memorial Research Hospital, for the treatment and care of persons afflicted with Bueyer's disease, and for experimental and scientific study of such diseases and the medicinal and curative properties of the waters of Soap Lake.

COUNTY GENERAL HOSPITALS.—Laws were enacted in Alabama ⁵⁵⁹ Florida, ⁵⁶⁰ Iowa, ⁵⁶¹ Kansas ⁵⁶² and South Carolina ⁵⁶³ authorizing the establishment of county hospitals in stated counties in the states in question. The new Alabama law authorizes the establishment and operation of a county hospital in Cullman County. One of the Florida laws ⁵⁶⁴ provides for the establishment of a county general hospital in counties of from 9,000 to 11,000 population, while the other Florida laws authorize the establishment of such hospitals in Jackson, Leon, Pasco and Putnam counties. The Iowa law authorizes such hospitals in any county having a population of 135,000 or more. The Kansas law applies to a county of from 100,000 to 140,000 population containing a city of from 90,000 to 115,000 population. The first South Carolina law cited authorizes the establishment in the county of Charleston of such a hospital which can serve not only charitable patients but also pay patients at such rates as are commensurate with the ability of the patient to pay. The other South Carolina law authorizes a county hospital in Colleton County.

A new Wyoming law ⁵⁶⁵ permits county hospitals to treat pay patients at such rates as the hospital boards deem equitable.

A bill to accomplish a similar purpose was killed in California.⁵⁶⁶

COUNTY TUBERCULOSIS HOSPITALS.—A new North Carolina law ⁵⁶⁷ authorizes counties to establish and operate hospitals for the treatment of tuberculosis.

An unsuccessful attempt was made in Texas ⁵⁶⁸ to authorize the board of county commissioners of any county having a population of more than 30,000 to establish and operate a hospital for the treatment of tuberculosis.

DISTRICT TUBERCULOSIS HOSPITAL.—A new Illinois law ⁵⁶⁹ sets forth the procedure whereby any two or more contiguous counties may be incorporated as a tuberculosis sanatorium district and may establish and maintain a tuberculosis sanatorium, and branches, dispensaries and other auxiliary institutions connected with it within the limits of the district.

MUNICIPAL HOSPITALS.—A new Minnesota law ⁵⁷⁰ authorizes any city of from 2,700 to 2,800 population to establish and operate a general hospital.

Two other proposals were killed, however, in Minnesota ⁵⁷¹ to authorize the governing board of any village or city to cause a special election to be held for the establishment and maintenance of a municipal hospital. If the election was favorable, the bill authorized the establishment and operation of such a hospital.

A new Kansas law ⁵⁷² permits a particular city with a population of from 3,750 to 4,300 and located in a county of from 16,000 to 21,000 population to establish a city hospital.

VIII. WORKMEN'S COMPENSATION LEGISLATION

A. New Act

A law was enacted in Arkansas ⁵⁷³ providing compensation for employees for disability or death resulting from accidental injuries arising out of and in the course of employment and such occupational disease or occupational infection as arises naturally out of such employment or as naturally or unavoidably result from such accidental injury. The employer must furnish to the disabled workmen "such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus as may be necessary during sixty days after the injury or for such time in excess thereof as in the judgment of the [Workmen's Compensation] Commission may be required." Apparently, the injured workman is to be entitled to select his own physician only if an employer fails or neglects to provide one or in the case of emergency. The law specifically provides that a person rendering medical, surgical or other attendance or treatment, nurse or hospital service or emergency treatment must submit his proposed charges to the commission for its approval.

The new law is subject to a statewide referendum in November 1940, and its operation is suspended subject to the outcome of that referendum.

B. Changes in Present Compensation Acts

INJURIES COMPENSABLE.—New occupational disease compensation acts were enacted in Idaho, ⁵⁷⁴ Maryland ⁵⁷⁵ and Pennsylvania.⁵⁷⁶ The new Idaho law pro-

572. Kan., Laws, 1939, c. —, approved April 3, introduced as H. 342.

573. Ark., Laws, 1939, Act 319 (S. 41, H. 222 and S. 426, somewhat similar bills, were also considered but failed of enactment).

574. Idaho, Laws, 1939, c. 161.

575. Md., Laws, 1939, c. 465.

576. Pa., Acts, 1939, Act. No. 284.

vides compensation for some eleven stated types of occupational disease while the new Pennsylvania and Maryland laws respectively provide compensation for some twelve and thirty-four stated types of occupational disease. The new Maryland law sets up a medical board to consist of three physicians to be appointed by the governor, whose duty it is to pass on all claims for compensation for occupational disease and to conduct such physical and x-ray examinations of claimants as it deems necessary and to certify its findings to the state industrial accident commission.

Provisions of the workmen's compensation acts of Minnesota,⁵⁷⁷ Ohio⁵⁷⁸ and Washington⁵⁷⁹ providing compensation for stated occupational diseases were amended this year. The new Ohio law extends the list of occupational diseases which are compensable and in effect makes compensable all diseases arising out of employment. The new Minnesota law adds to the list of compensable occupational diseases "the following occupational diseases due to the hazards of fire fighting, myocarditis, coronary sclerosis, and pneumonia or its sequelae in firemen." The new Washington law provides compensation under stated circumstances for asbestosis, silicosis (including anthracosilicosis and silicotuberculosis) and any respiratory disease contracted through the inhalation of dust.

A bill was killed in Oregon⁵⁸⁰ proposing to make compensable all occupational diseases arising out of and in the course of employment. Bills to extend the list of compensable occupational diseases or to make stated occupational diseases compensable were killed in Delaware,⁵⁸¹ Georgia,⁵⁸² Montana⁵⁸³ and Pennsylvania.⁵⁸⁴ Unsuccessful attempts were made in New York⁵⁸⁵ to include within the workmen's compensation act employment in hospitals.

MEDICAL AND HOSPITAL AID.—Laws increasing the amount of medical, surgical and hospital aid to be rendered an injured employee at the employer's expense were enacted in Arizona,⁵⁸⁶ New York,⁵⁸⁷ North Dakota,⁵⁸⁸ South Dakota⁵⁸⁹ and Texas.⁵⁹⁰ The new Arizona law provides for such medical and hospital services as are reasonably required to be rendered the injured employee. The prior law limited this care to the first ninety days after the industrial accident. The new New York law enables an employee disabled by an occupational disease resulting from the inhalation of harmful dust to receive at the expense of the employer medical treatment for a period of up to 270 days. The new North Dakota law requires the state fund to furnish an injured employee such medical, surgical and hospital services and supplies as the nature of the injury may require and such artificial limbs, glasses, braces or appliances as may be necessary to rehabilitate the employee. The new South Dakota law raises to \$300 the maximum liability of an employer for medical and hospital services rendered an injured workman and extends the period after the industrial accident during which the employer must provide such services to twenty weeks. The new Texas law requires an

employer's insurer to provide medical and hospital services to an injured workman where needed up to ninety-one days from the date of the injury and in hospital cases, and if the attending physician certifies to the necessity thereof hospital services must be provided for two weeks longer.

Bills to increase the amount of medical, surgical and hospital aid to be rendered an injured employee at the employer's expense were killed in four other states.⁵⁹¹

RIGHT OF EMPLOYEES TO CHOOSE PHYSICIANS.—Bills were killed in six states⁵⁹² which proposed to permit an injured employee to select the physician whom he desires to treat him for his industrial injuries and to make the employer liable for such medical and surgical aid as that physician deems reasonable or necessary.

EMPLOYERS' LIABILITY FOR CULTISTS' TREATMENT.—Bills were considered and killed in five states⁵⁹³ to amend respective workmen's compensation acts so as to permit osteopaths or cultists to render the required "medical" attention to injured employees.

IX. MISCELLANEOUS LEGISLATION

LABORATORIES.—Laws regulating the operation of stated types of laboratories were enacted in Maryland⁵⁹⁴ and Massachusetts.⁵⁹⁵ The new Maryland law authorizes the state board of health to establish such a minimum standard as it considers necessary for laboratories in the state, except in Baltimore, which make examinations in connection with the diagnosis and control of human diseases. The new Massachusetts law authorizes the department of public health to issue on request certificates of approval to bacteriologic laboratories and to specify in the certificates what bacteriologic or serologic procedures performed in such laboratories are approved by the department.

A new California law⁵⁹⁶ repealed the prior law regulating the production and distribution of serums, vaccines, bacterial cultures and viruses and enacted a new act prohibiting the production of such substances except in laboratories licensed either by the state department of health, the U. S. Public Health Service or the Bureau of Animal Industry of the U. S. Department of Agriculture.

BLOOD GROUPING TESTS.—Laws were enacted in Maine,⁵⁹⁷ New Jersey⁵⁹⁸ and Ohio⁵⁹⁹ providing that whenever it is relevant in a proceeding involving the parentage of a child, the trial court may direct the mother, the child and the defendant to submit to one or more blood grouping tests to determine whether or not the defendant can be excluded from the probability of being the father of the child. The results of such tests are to be admissible only in cases in which exclusion is established.

Similar bills were killed in two other states.⁶⁰⁰

The New York law permitting a court whenever it is relevant to the prosecution or defense of an action to direct any parties to the action and the child of any such party and the person involved to submit to one or

more blood grouping tests was so amended this year⁶⁰¹ as also to permit a court to order such a test "whenever it shall be relevant in any proceeding pending in a court of record."

TRAFFIC CODES—ADMISSIBILITY OF BLOOD TEST TO PROVE OR DISPROVE INTOXICATION.—Laws were enacted in Indiana⁶⁰² and Maine⁶⁰³ making admissible in the trial of any person accused of operating a motor vehicle while intoxicated evidence of the percentage by weight of alcohol in his blood at the time of the alleged commission of the offense. The Indiana law provides that evidence that there was at the time in question 0.05 per cent, or less, by weight of alcohol in the blood is prima facie evidence that the defendant was not under the influence of intoxicating liquor sufficiently to lessen his driving ability. Evidence that there was, at that time, from 0.05 per cent to 0.15 per cent is relevant evidence but is not to be given prima facie effect as to intoxication. Evidence, however, that there was at that time, 0.15 per cent, or more, is prima facie evidence that the defendant was under the influence of intoxicating liquor sufficiently to lessen his driving ability. The Maine law is quite similar in this regard except that it states that evidence of 0.07 per cent, or less, by weight of alcohol is prima facie evidence that the defendant was not under the influence of intoxicating liquor and that evidence of from 0.07 per cent to 0.15 per cent is relevant evidence but is not prima facie evidence as to intoxication.

Bills similar to the Indiana law were rejected in Florida⁶⁰⁴ and Illinois.⁶⁰⁵

CORONERS AND MEDICAL EXAMINERS.—A new Maryland law⁶⁰⁶ repeals the prior law relating to coroners and creates a new executive and administrative department to be known as the Department of Post Mortem Examiners, the head of which is to be a commission consisting of the professors of pathology of the University of Maryland and of Johns Hopkins University, the director of health of the state, the commissioner of health of Baltimore city and the attorney general. This commission is authorized to appoint three medical examiners, who must be licensed doctors of medicine and have had at least two years of postgraduate teaching in pathology. The commission is also authorized to appoint a deputy medical examiner, who also must be a licensed physician, for each county of the state. Whenever any person dies as a result of violence, or by suicide, by casualty, suddenly when in apparent health, when unattended by a physician, or in any suspicious or unusual manner, it is to be the duty of the police or sheriff immediately to notify the chief medical examiner or a deputy medical examiner, who is then to go to the dead body, take charge of it and investigate the essential facts concerning the circumstances of death. If an autopsy is deemed necessary, it must be performed by the chief medical examiner, by the assistant medical examiner or by such competent pathologists as may be authorized by the chief medical examiner.

Unsuccessful attempts were made in Delaware⁶⁰⁷ and Michigan⁶⁰⁸ to abolish the office of coroner and to create a medical examiner system in the state.

The medical examiner laws of Maine,⁶⁰⁹ Massachusetts⁶¹⁰ and Rhode Island⁶¹¹ were amended this year. The Rhode Island amendment provides, among other things, that if the medical examiner believes that a death was caused by the act or neglect of some person other than the deceased he must notify the attorney general and the police of the jurisdiction in which the body was found and must file a copy of the record of his autopsy, or view, with the attorney general. The medical examiner must also in all cases certify to the officer having custody of the records of deaths in the town in which the deceased came to his death the name and residence of the deceased, if known, or, if not known, a description of the deceased together with the cause and manner by and in which he came to his death. The Massachusetts amendment permits a medical examiner to perform an autopsy on any dead body in his county on the written order of the district attorney. The prior law permitted an autopsy only on the body of a person supposed to have died by violence. The Maine amendments increase the number of medical examiners in stated counties and seem to require a medical examiner to obtain the authorization of the county attorney or the attorney general, before performing an autopsy.

Unsuccessful attempts were made to amend the law relating to coroners in four states.⁶¹² One of these bills⁶¹³ proposed to create the office of medical referee for each county in the state. The medical referee was to be a licensed physician whose principal duty it was to determine as to whether it was necessary for the county coroner to hold an inquest on the remains of any deceased person. Another one of the bills⁶¹⁴ proposed to authorize the judges of the superior court to appoint for each county a coroner and a deputy coroner, who must be attorneys at law.

ANIMAL EXPERIMENTATION.—An unsuccessful attempt was made in New Jersey to amend the law relating to vivisection.⁶¹⁵ The bill proposed that the law making it a misdemeanor to inflict unnecessary cruelty on a living animal should not be construed to prohibit or interfere with properly conducted scientific experiments performed under the authority of the state department of health. The present law apparently limits the institutions or societies which the department may authorize to conduct such experiments by stating that the department may authorize such experiments to be conducted by agricultural stations and schools maintained by the state or federal government or by medical societies, universities, colleges and philanthropic institutions incorporated or authorized to do business in the state and having among their corporate purposes investigation into the causes, nature, prevention and cure of diseases.

ASEXUALIZATION.—The legislatures of four states having no compulsory sterilization statutes considered and killed bills seeking to require the sexual sterilization of insane, idiotic or imbecilic inmates of state institutions.⁶¹⁶ One of these bills⁶¹⁷ in addition, provided for the asexualization of persons who had been convicted a second time of a sex crime.

The legislatures of five states having compulsory sterilization laws considered and killed bills to amend or supplement existing sterilization statutes.⁶¹⁸

OFFICIAL NOTES

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Second Annual Meeting, held in Chicago, Jan. 15 and 16, 1940

(Concluded from page 898)

DR. CLARENCE D. SELBY, Detroit, in the Chair

JANUARY 16—MORNING

PHYSICAL EXAMINATIONS

Objectives of the Health Examination and Their Industrial Application

DR. McIVER WOODY, New York: In 1861, Horace Dobell, of London, came forward with the proposition "that there should be instituted, as a custom, a system of periodical examination, to which all persons should submit themselves, and to which they should submit their children." Little came of Dobell's suggestion, and the whole idea was forgotten for half a century. It was not until the army applied physical examinations on a large scale during the World War that data were available on the physical condition of those gainfully employed. After the World War, periodic examinations were introduced from time to time by certain large industrial organizations. Not too much was expected of them at first, but it was soon found that the examination was of immediate benefit, thanks to the effectiveness of modern treatment.

What is the best routine to follow when it comes to applying the periodic examination in industry? If the employee has been with the company for some years, there will be information concerning him in the files of the medical department. If records of the man's visits to the office are kept in ledger fashion, with a separate sheet for each employee, so that everything of a medical nature pertaining to that one individual can be found in one place, it will be no trouble for the nurse to place the man's folder on the doctor's desk so that he can glance through it rapidly before stepping into the examining room. To provide a favorable atmosphere for an examination that goes beyond the routine search for organic disease, it is advantageous to develop an informal approach, which must prevail from the moment the patient presents himself at the doctor's office. The nurse should let the patient feel that he is expected and very welcome, as she ushers him into the examination room, where he should be given a few minutes of quiet to prepare himself for the interview. I make it a practice to begin the examination by taking the blood pressure, partly because this is something that every layman is interested in and partly because it gives me a good opportunity to put the patient at his ease and inspire his confidence. Even the taking of the pulse I try to do in a way that indicates my personal interest. The examiner may vary the routine in some instances, provided he always carries two things in mind, to omit no essential part of the examination and to give the patient the feeling that this examination is intended solely for his benefit.

While the patient is dressing, the examiner may find it helpful to linger for a few moments while he reviews his observations, but as a rule he should not leave the examining room until he has given the patient a clear idea of the results of the examination and rather definite advice as to what he should or should not do about any defects which may have been brought to light by the check-up. This informal approach to the patient and his problem is more convincing than an impersonal attitude and we believe the patient is more apt to accept advice given him then. The examiner should seek to inspire confidence by the care and thoroughness of the whole procedure, and he should encourage the patient to feel that the physician's entire attention is concentrated on him, without any thought as to other pressing duties.

A man may not welcome the news that an incipient hernia has been discovered, but he is entitled to the information then and there, provided it is told him in a helpful manner. If he is alarmed over the possibility of operation, it may be well

worth while to go into details of what may happen without operation and explain to him the advantages of having the inguinal canal restored to its original size before such a procedure becomes an emergency necessity. This holds true for diseased tonsils, diseased teeth and many other lesser conditions which can be treated successfully by modern dentistry and surgery. The problem is much more complicated when it comes to a question of heart or kidney disease. But even here it is nearly always possible to give the patient a fairly good idea of the health problem with which he is confronted. Indeed, it is surprising to see just how much information can be given a patient with benefit to him, if the subject is approached in a sympathetic spirit. These two instances serve to show that once the man realizes that a periodic examination is of a real benefit to him he will welcome the opportunity to come back year after year, especially if he knows that each time he is examined the observations will be compared with those at previous examinations; that even a slight variation in weight will elicit a certain amount of interest. In this way his interest can be aroused in the general principles of diet, exercise and recreation.

I have been considering the periodic examination mainly from the standpoint of the employee. To the company doctor, periodic examinations can be helpful in several ways. By devoting a few hours of each day to this part of the work, he can follow his cases through the years with a persistence that is beyond the reach of the clinicians in the best teaching hospitals. If the plant physician can give each employee his undivided attention for even fifteen minutes every year, he should be able to build up a personal friendship with them all. This gives the employees a real incentive to report industrial accidents promptly, and even the most trivial accident can have serious consequences in the way of infection, all of which could have been prevented by treatment given immediately after the accident occurred. The same considerations apply in industrial disease. Perhaps the greatest benefits are reaped from this confidence among employees when some unforeseen accident occurs; for it is then that the company doctor, who is thoroughly acquainted with the plant and the men in it, proves his worth. Of course, the employer's interest will be served by anything which benefits the individual employees. The days they are away from the job affect his annual statement just as truly as they do the savings accounts of the employees.

Finally, the plant physician will do well to consider the periodic physical examination as a problem in human engineering. As the engineer who designs a bridge takes care to do his work thoroughly but not in ponderous fashion, so the plant physician must take care not to make his examinations too searching, too prolonged and too theoretical. It might be helpful to mention the engineering rule that "good enough is best." Even though the employer might be willing to have the plant physician set aside more time for each periodic examination, it would not necessarily follow that an examination which took twice as long would be twice as valuable. The attitude of the employees to the examinations is important, for it would defeat their purpose if the employees came to the conclusion that they could not spare the time to be looked over because they had work to do. On the other hand, if the examinations are too superficial they fail to inspire confidence, and again the employees will begin to question whether the examination is worth while. Both extremes must be avoided. If the industrial physician is to be of lasting value in industry, he must think of himself as a medical engineer building the periodic health examination into a strong bridge to span the gap between medical knowledge and its application in industry.

The Private Practitioner and Industrial Physical Examinations

DR. RAYMOND HUSSEY, Baltimore: The physician making an industrial examination is on the lookout for the possible existence of presymptomatic or subclinical conditions and reactive disease, as well as active disease. The decision must be made regarding the fitness of the individual for employment.

and in many instances for a particular employment. So there are fundamental differences in the usual clinical responsibilities of the physician and those he must assume in connection with industrial physical examinations. During a symposium on occupational diseases in 1938 conducted by the Department of Industrial Medicine of the Northwestern University Medical School the subject of industrial physical examinations was presented by Selby; the subject of the relation of the private practitioner to industrial health and safety was presented by Seeger. Among the shortcomings of private practitioners engaged in industrial medical work, attention was called to their lack of knowledge about occupational disease hazards in the plants they serve. As a result of this they have failed in many instances to suggest to the management the desirability of surveying the industrial environment, and they are unable to make recommendations regarding the safety of placing individuals in particular jobs. In spite of this state of affairs, it is brought out that private practitioners furnish services to about 85 per cent of the industrial establishments in the United States and that the work of this group has been essentially case work and basically remedial in nature.

I agree with the criticisms made and I wish to make the following recommendations to improve conditions which provoke them:

1. That opportunities be offered medical students to work during vacation periods in medical departments of industries, just as such vocational opportunities are offered by industry to students of engineering and technical schools.

2. That formal and practical work in industrial hygiene be considered a prerequisite for physicians who expect to include industrial medicine in their practice.

3. That physicians already in industrial medicine cooperate more actively with their state and local health departments in such efforts as are made by those agencies to develop activities in connection with the control and prevention of occupational diseases. In particular that they find a way to comply more fully with any law requiring the reporting of occupational diseases.

4. That state, city and county medical societies should recognize the responsibility of medicine to industry as outlined in the several bulletins published by the Council on Industrial Health of the American Medical Association.

5. That medical societies initiate health examination programs in industry or cooperate with industry, labor and public health agencies in their development.

6. That these societies make an especial effort to bring to the attention of physicians the facts known concerning the silica hazard and the incidence of silicosis, the methods for its control and the pitfalls in its diagnosis.

7. That these representatives of organized medicine initiate movements to improve standards of medical practice in industry. Particularly, that a real effort be made to control medical and legal racketeering in connection with injuries and disease alleged to be a consequence of an occupation.

8. That, in the presentation of diseases which may result from occupational hazards, clinical teachers in our medical schools give more emphasis to the preventive aspects and to the community responsibilities of physicians in these special problems of medical care.

9. That medical schools as far as possible include in their curriculums more adequate instruction in industrial medicine or organize to better advantage what is now included.

Industrial medicine as a special field of interest is much like public health and requires curricular arrangement that more closely allies it with the teaching of preventive medicine in general. Medical school administrators as well as the students themselves have become aware of health hazards in scholastic and hospital work. The entrance requirements of many medical schools give equal emphasis to health and scholastic preparedness. In this manner the preadmission health examination and subsequent reexamination are becoming a matter of established fact and of recognized necessity. This together with improvements in methods of teaching anatomy and physiology

and the development of clinics for the first and second year medical students where health is given emphasis will have a decisive influence in developing a point of view and an attitude for the student to understand the requirements of industrial medicine.

I believe that private practitioners will rise to the occasion when the demand is made for their services to participate in a program of health examinations for industry. At times, when there has been a general mobilization of our armed forces, private practitioners have adapted themselves quickly and efficiently to the requirements of military medicine, and I see no reason to think that they will do differently in the case of industrial medicine.

The problem of reemployment following temporary disabling illness deserves careful consideration. It is interesting to speculate on how the results of a wide scale physical examination program among industrial employees will influence the unemployment problem. Interesting also is the thought of how the results may affect rehabilitation programs and facilities.

A word about the examination: Fluoroscopic examinations and x-ray films of the chest should be required. Each examination should be divided among several medical men, each one of whom will be responsible for a particular part of the examination. Also I would stress the fact that physical-mental relationships must be kept in the foreground, since fitness for work and living depend equally on mental and physical health.

The Wisconsin Program of Preemployment and Medical Examination Procedure

MR. HARRY A. NELSON, Madison, Wis.: The Wisconsin statute required that employers should furnish employment and places of employment which should be safe for employees, should furnish and use safety devices and safeguards, should adopt and use methods and processes reasonably adequate to render employment and places of employment safe, and should do "every other thing reasonably necessary to protect the life, health, safety and welfare of such employees and frequenters." Further, employees should not remove, displace, damage, destroy or carry off any safety device or safeguard furnished nor interfere with their use, nor should they interfere with the use of any method or process adopted for the protection of employees "nor fail or neglect to do every other thing reasonably necessary to protect the life, health, safety or welfare of such employees or frequenters."

Different interpretations were given to safety statutes by the courts. Those courts which gave liberal interpretations from the standpoint of workers held not only that the physical equipment of the plant was required to be maintained in a safe condition but also that the workers themselves should be so chosen and supervised as to comply with the safe place and safe method statutes.

When analysis is made of statistical data covering accidents, it is observed that many of them occur because of the failure of the human factor. When we ask as to the manner in which this human element of unsafety is to be eradicated, we conclude that the least that can be done is to examine the worker at the time he enters employment and to reexamine him at reasonable intervals. Labor organizations have from time to time raised their voices against physical examinations of their members. Their protest has not been entirely without foundation. Happily, the vast majority of employers, and increasingly so, have exhibited sympathy and beneficence, if not always intelligence, toward their employees, sometimes even to the point of doing them harm by putting disabled persons in positions where they should not be. A middle course is indicated which will avoid prejudice to employees and reasonably safeguard the employers' interests.

Before the adoption of the physical examination program there had been written into the Wisconsin law provisions intended to discourage oppressive plans of physical examination and rejection of employees or applicants for employment. It was provided that the advantage of experience rating and consequent lower rate of premium for compensation insurance is to be forfeited by the employer who applies an oppressive plan

of examination. Self insurers are deterred from operating such plans by a provision granting the industrial commission power to revoke the exemption from insurance of the employer who institutes them. Insurance carriers under similar provisions may have their licenses revoked if they "encourage, persuade or attempt to influence any employer arbitrarily or unreasonably to refuse employment to or to discharge employees." A further provision is for benefits to one discharged from work because of nondisabling silicosis, unless it has been found by the commission that it is inadvisable for the employee to continue in employment.

To answer the objections of labor organizations and of employers, reasonable standards and safeguards must be formulated under which examinations are to be conducted. Their scope and their use must be clearly defined. An agency must be stipulated for purposes of arbitration in event claim is made of misuse of the examination privilege. For years Wisconsin has considered this subject. Two years ago the commission called a conference including representatives of labor organizations, employers, physicians and insurance companies to consider the possibility of setting up a program of physical examination of employees in this state. Committees were appointed to consider the various phases involved. One of these committees was a medical committee, the representatives of which were chosen by labor, by industry and by the industrial commission. A dozen meetings were held at which prolonged consideration and study was given to the subject. As a result of these deliberations the main committee presented a report, after which the industrial commission adopted the Wisconsin physical examination programs. The plan is in no way compulsory. The fact that it has been generally approved by representatives of interested parties leads the commission to believe that it will be widely adopted.

Under the plan all physical examinations are to be made by physicians selected by the employer. If there is a grievance on the part of the examined employee, the industrial commission on proper complaint will cause investigation to be made, and if the grievance is found to be justified the employer is to cause further examination of such employee to be made by another physician. The report urges that any practice inconsistent with the plan be presented to and acted on by the industrial commission. For such purpose the commission may appoint an advisory committee to be composed of representatives of labor, of industry and of the medical profession. Examinations are to be paid for in full by the employer, including lost time or transportation expense occasioned by examinations to employees in service. Preemployment examinations should be made prior to employment if possible. It is recognized, however, that there may be uncertainty as to qualifications other than physical fitness, so a test period is provided to enable the employer to learn of the employee's qualifications and to delay preemployment examination in such cases for a period not in excess of thirty days.

The medical subcommittee concluded that a program of this type should cover all types of industries. Protection of health and improvement in the physical well-being of the workers was first in their minds. Improvement in the economic status of workers as the result of protection of health is reflected in the reduction of time and wage loss resulting from ill health, and any program that tends to improve and protect the health of industrial workers tends to reduce the incidence of occupational accidents and diseases. With these principles in mind the committee adopted a report covering scope of examinations, reexaminations and specified procedures for different types of employment. In addition to physical examination, laboratory procedures are to include a chest roentgenogram (flat plate), blood serologic study for the diagnosis of syphilis, urinalysis for sugar and albumin determinations only, and blood examination.

One of the occupational diseases which today calls for large payment of benefits in Wisconsin is that of dermatitis caused by contact of individuals with substances used in their work. The program is not to be static. It is elastic and calls for continued study of specialized processes and of education of

physicians to the awareness of the changing hazards brought on by progress in industrial operations. To insure success there must be the closest cooperation on the part of medical men and their organizations with labor and industry and unceasing vigilance by all in the discovery of newer and better practices as available. The subcommittee recommended that the original examination form be retained by the examining physician for his own record and that no other similar form be issued to either employee or employer. However, the employer and the employee should be informed of any defects which are found. So the report which is given to the employer and employee contains a notation as to physical defects (other than lungs), visual defects and, when pertinent, a further notation as to lung examination, with suggestions and recommendations.

Always it is to be stressed that the employee is to be considered a personal patient and treated as such by the examining physician. The relationship between these parties is that which should always exist between physician and patient. The employee's family physician is entitled to the full report of the examination so that he may intelligently treat his patient. When defects of a private nature are discovered, treatment is to be insisted on, and state and local laws covering treatment are invoked if the employee refuses to accept proper treatment.

The committee concluded that because of statutory provisions it was beyond its jurisdiction to prevent the admission of any examining physician's report as evidence in a compensation case. The use of the report in compensation cases will result in an honest factual determination, and the question of a pre-existing condition or of aggravation will be given careful consideration by the commission. Use of the report will in no way prejudice the applicant, provided his claim is legitimate, and will in many cases assist him in establishing his claim by dispelling doubt as to a previous condition.

The program adopted is open to modification as often as required. It is an innovation of a pioneering nature. With the modifications which experience may suggest, we believe it will result in increased prevention of accidents and disease, in a happier placement of employees in work, and in the greater social and economic good of employer, employee and the state.

Scope and Methods of Industrial Physical Examinations of the Wisconsin Plan

DR. PAUL A. BREHM, Madison, Wis.: To promote an industrial health program, a medical subcommittee was appointed to consider a schedule of preemployment physical examinations and subsequent periodic reexaminations for workers in Wisconsin industries. I shall consider only the deliberations of the medical committee on the five points covered in the recommendations.

1. *Scope of Examinations to Be Made, Including Preemployment and Subsequent Examinations and Periodic Reexaminations.*—Much of the discussion during the committee meetings involved extending the scope of the examinations to include all industries, and also the inclusion of a chest roentgenogram as a routine diagnostic measure. It was felt that this is essential in making a diagnosis of tuberculosis, and from the standpoint of reducing the incidence of this disease the procedure was recommended. A routine x-ray study of the chest was considered important for the control of tuberculosis in any occupational environment. A flat plate was considered sufficient for routine examinations, whereas stereoroentgenograms may be necessary only in questionable cases of active tuberculosis or for the purpose of consultation. The importance of routine serologic examination of the blood for the diagnosis of syphilis is advocated for the protection of the infected individuals and prevention of spread of the disease. Syphilis in an infectious stage indicates adequate treatment before the infected person can engage in any occupation. Syphilis in a noninfectious stage should not exclude the patient from employment but should call for medical control. In industries presenting excessive hazards or hazards the nature of which requires frequent special laboratory investigation, it will be necessary to reexamine the individual, the interval of time depending largely

on the judgment of the examining physician; where only specialized procedures are frequently employed, the general physical examination need not be made except at the two year intervals. Specialized procedures for different types of employment to determine ill effects of exposures on workmen will necessitate supplementary information to be used by the examining physicians. It is advisable that a manual be prepared containing special diagnostic measures and physical examination guides for the various specific industrial hazards. The medical committee was of the opinion that of the greater importance in a new venture of this kind was to advocate a general program of physical examinations in all types of industries, thus laying the foundation on which to build soundly in the future.

2. Form of Reports to Be Made by Physicians.—Sample form A, advocated for reemployment and periodic reexaminations, includes personal history, occupational history, past medical history, spaces for recording the results of a complete physical examination and the required laboratory measures, space for special examination procedures, name of the physician making the x-ray study, name of the family physician, name of the examining physician and corresponding sections for four examinations. Sample form B is included for reporting the results of the examination in duplicate to both employer and employee.

3. Whether or Not the Report Should Be Supplied in Its Original Form to Employer and Employee.—The clinical judgment of the examining physician will determine the extent of information furnished to employer and employee. To report minor or unimportant data may create misunderstanding or fear. Only those significant defects which directly affect the employability of the applicant or which, if corrected, would benefit his physical well-being, are of major importance in an examination report.

4. Reports in Compensation Cases Covering Injuries Claimed to Have Arisen After the Time of Examination.—Because of statutory provisions it is beyond the jurisdiction of the medical committee to prevent the admission as evidence in a compensation case of any examining physician's report. Attention again is called to the fact that the examining physician's report of the physical observations is made in duplicate, the original to the employer and a copy to the employee. This routine may preclude the possibilities of either too widespread use of reports in compensation cases or having the reports fall into unscrupulous hands.

5. What Conditions Shall Influence Employment.—The committee felt that diseases, deformities and disabilities are too variable in degree and extent to permit of a practicable schedule. In such matters the clinical judgment of the examining physician must control, for with him rests the decision of evaluating physical fitness of an individual. To include a long list of diseases and disabilities in the medical committee report might serve to defeat the program. The physician will find those applicants who are physically fit for any occupation, those who are fit for any job but have some minor and correctable defects, those who because of defects must be limited as to occupation and need medical supervision but not necessarily medical attention, and finally those who because of disabilities will be unable to work and who will require medical attention. Examples of the latter group are persons disqualified for work because of (1) active tuberculosis, (2) syphilis in the infectious stages until proof of adequate treatment is submitted, (3) communicable or contagious diseases of any kind until recovery is complete, (4) hypertension only when associated with damaged heart or kidney function or both, and (5) serious defects of vision or hearing in hazardous employment where the safety of others depends on the physical fitness of such afflicted persons.

The schedule of physical examinations proposed by the medical subcommittee is a voluntary plan, and industry has a choice of adopting the program in whole or in part or of rejecting it entirely. The committee attempted to formulate a practical plan of physical examinations to apply to workers in all industries. For the benefit of physicians who will make the exam-

inations and pass judgment on the physical fitness of the applicants, it is essential that they familiarize themselves with all the environmental factors within the plants they supervise. The program is a beginning in the direction of rendering a necessary service to industry and labor. The medical committee hopes that it will be a real factor in the improvement of the health and safety of industrial workers.

DISCUSSION ON PHYSICAL EXAMINATIONS

DR. NATHAN DAVIS, Chicago: I agree with Dr. Woody that it is important to make these examinations personal in character and stress the individual employee. The examiner should be a consultant, who stands between the personnel department and the employee in determining his fitness for certain work and should also work closely with the family physicians and see if there are correctable defects or defects that need observation. Of course, any disease condition or mental worry has a bearing on the efficiency of the employee and may contribute to the failure of the human element. If the plant examiner will take a personal interest in the employees, nervous reactions will be minimized. I feel, as Dr. Hussey said, that the preemployment and periodic examination of all employees should be stressed, and I think that the employer and the office force should be included. The family doctor's lack of knowledge of the working conditions often makes it inadvisable for him to be the plant examiner. The fact that he has a personal interest in the care of the patient is not so important as his ignorance of conditions of employment. I agree with Dr. Hussey that in medical school and afterward, through the efforts of the medical societies, instruction and preparation for the work of a plant physician should be given to men in active practice because many industries have so few employees that they cannot afford to obtain the services of a specialist in that field. Cooperation with the health department is important. The statement that in medical education too much attention is paid to disease and not enough to health is worth stressing not only in industrial medicine but in all medical practice. I agree that x-ray films of the chest should be made in all cases. The cost is rather high, but the development of some of the newer methods for using small film will remove the economic objection to a large extent. The Wisconsin program, so far as it is a voluntary plan being urged on all industry in the community, is of great value. It stresses the importance of the failure of the human factor in the causation of accidents, and general inefficiency in industrial work. One type of examination was not particularly mentioned, and that is a reexamination of men, particularly of those in the older age groups who have been laid off for a time; such periods of inactivity may greatly impair efficiency, particularly of the older men. The examination of the man who has had a layoff is of tremendous importance in preventing difficulties thereafter and in eliminating claims. These examinations, to be universal, must be relatively simple, from the point of view of expense and the time required in making them. An employer in discussing this matter said that it was tremendously valuable if the management group would submit to examinations of the same type that were required of employees, before the employees were examined. When the employees saw that the employers felt these examinations were of value to themselves, it lessened some objection. The other objection on the part of labor will be removed if all men are treated alike, that is, if all with certain defects get the same treatment provided they have been working at the same jobs. They object also to being reclassified, but it is necessary for their own sake if not for the sake of the other employees. In communities where there are industries in which there is a dust hazard, the examination of not only employees but all citizens of the community is important to eliminate tuberculosis from the plant and from the community. The examination of record may well be made available to the family doctor, although reports such as Dr. Brehm describes would be sufficient for the patient and the employer; that is important, as it might gain more cooperation from the family doctor and would give the information for his record which he might not have if the patient remained well.

DR. A. G. KAMMER, East Chicago, Ind.: I noted that the Wisconsin plan recommended a reexamination at two year intervals. I wonder if that is an arbitrary position or whether there is experience behind the decision. I should be glad to know exactly the most practicable intervals for making reexaminations. It would be of interest to know how long an interval passed between the first examinations of the 1,000 men reported by Dr. Woody. The incidence of positive results and the percentages reported at a short interval, for instance, would indicate that reexaminations at short intervals are in order. If, on the other hand, the interval was a long one, it wouldn't mean so much. All interested in this type of work spend time occasionally in arriving at the score, such as Dr. Woody did for us this morning. I think that as time goes on and we more or less begin to report percentages of data we are going to find wide disagreements. His figure of 6 per cent of diagnosed respiratory diseases impresses me as being low. His observation of 12 per cent of men afflicted with disease of the cardiovascular system strikes me as being low. The thing we need to know here is the age of the men and the length of time it took the condition to develop. It doesn't do much good to argue about whether one failure is right, or another, until we start using the same diagnostic procedures and then decide on terminology. I think one of the functions of this group should be to draw up a more or less precise form of language to be used when we get together and talk about our work and compare results. The remark was included in Dr. Woody's paper, in connection with industrial health examinations, that good enough is best. Probably that is a rather practical way of viewing it. On the other hand, the worker in the plant where examinations are regularly made begins to rely on what is told him at the end of each examination, which may come up at the end of every year or every two years, and if you miss some diagnosis the man is probably going to go along and ignore warning symptoms too long. There, again, what is the right thing to do and how far to go are matters which probably have to be settled individually. I was pleased by the extent of the examination recommended by the Wisconsin group. I am wondering why sedimentation rates were not included as routine laboratory procedure. In some 14,000 examinations made in our plant, I think the diagnosis of leukemia has been made once, and the diagnosis of pernicious anemia twice, so I wonder at the practicality of doing a blood smear when looking for conditions of that type. The sedimentation rate, on the other hand, has proved enormously useful in helping us decide who is healthy and who isn't. True, it doesn't establish diagnosis, but it does tell us when our examining doctors have gone to sleep.

DR. J. W. DUGGER, Jackson, Miss.: Our examinations in Mississippi begin at home. Dr. Underwood, executive officer of the State Board of Health of Mississippi, says we must practice what we preach. We are required to turn in to him a record of the physical examinations of all the employees of the state board of health. This includes x-ray study of the chest, blood reaction and many other important points. We start in our own organization, and when I go into plants to sell my program the first thing I tell the employer and the employees is "We are not asking you to do any more than we have to do ourselves." The employer is seen and the program outlined to him. If I can sell my program to the employer, it is up to me to sell it to the employees. The employer will close down his machines when it is convenient and allow me to explain to the employees the benefits to be derived from these examinations. I explain the significance of the tuberculin test. Then I ask them if they would like to have this service and, in every instance, almost every hand will come up. I might add that the health officer in that county is seen, and if there is an industrial physician for that plant of course he is consulted and asked to cooperate. The procedure of our examination includes the personal history, name, address and vocation of the man or woman. What they do in the factory is recorded. Disease experience is also recorded. Each is asked if he has had typhoid immunization in the last three years or smallpox vaccination in the last five years. We examine the ears with

the otoscope and observe the nose and throat, as well as looking for gross defects of the teeth and noting whether pyorrhea, decayed teeth, or cavities are present, which are reported. We also examine the heart and take the blood pressure.

DR. WILLIAM J. SHERIDAN, Chattanooga, Tenn.: I come from an industrial city in the mid-South representing quite a few industrial plants, more from the workmen's compensation angle than anything else. A number of these industries have preemployment and periodic health examination. One reason I came to this meeting was to see if I couldn't get a better concept as to who is to be employed and who is not to be employed when the men come before me for physical examination. The problem of syphilis is about the only question that has been answered in my mind. I should like to have in the rest of the discussion something more concrete. I can sympathize with labor and with Mr. Zimmer that the average employee coming up for examination feels he may be turned down, and I think the doctor is taking a great responsibility on his shoulders when he refuses to employ some man who has a wife and dependents. True, that man represents quite an investment for the employer, but he certainly does represent an investment for his family. In further discussion I hope this will be touched on. I want to know what to do with the man 45 years of age who comes up for employment. Is he to be refused employment? I want to know what to do with the fellow with extensive fibrosis of the chest who doesn't have any symptoms. What am I going to do with the man with high blood pressure? What about the one who is overweight or underweight? How about the fellow who isn't in good physical condition and yet you can't put your finger on anything?

DR. J. J. BRANDABUR, Huntington, W. Va.: My remarks are the result of several years of study of the periodic physical examinations in the industry which I represent. There are some medical men who feel that the periodic examination should be voluntary and that it should be made by the family physician. I disagree first because the periodic physical examination was broached as a principle of the American Medical Association twenty-five years ago to the general practitioner, and he has been able to do little about it, so it was up to industry to lead the way. Secondly, people do not want any examination as long as they feel well, and usually by the time they begin to have aches and pains considerable damage has been done. What is more, requiring the family physician to pass on the physical fitness of the employee places too much of a burden on his shoulders. He is not conversant with the hazards of this man's job, as is the industrial physician. In numerous instances we have referred these men back to the family physician for treatment, and we receive a letter stating that the man's general condition is good for his age, but nothing is said about his ability to carry on his work, particularly if it is hazardous. The record of the periodic physical examination should be a matter of strict confidence between the employee and the medical department, and in no instance should a supervisory officer know the defects which are found unless the employee, as protection to himself, wishes them to be known. After all, the supervisory officer is interested in whether that man is able to perform his work efficiently, and even if he knew what the defects were he could not correct them. What is more, the records of these examinations should be kept under the supervision of the medical director and no one should have access to them. There are some who do not agree with me, but if you will discuss the matter with the progressive leaders of labor you will find that one of the greatest objections to either the preemployment or the periodic physical examination rests mainly on this question of secrecy. Labor leaders claim that too often, if the supervisory officer finds out about this or that employee's defects, the employer uses that knowledge as a wedge to get rid of the man. We have conducted the periodic physical examinations in our industry for several years with a great measure of success, and the management feels that one of the main reasons for this success has been that the reports of these examinations are a matter of strict confidence between the employee and the medical department. The reports

are kept under my close supervision. No one is permitted to see the report of any employee without authorization from the employee himself.

DR. CHRISTOPHER LEGGO, Crockett, Calif.: There has been little labor turnover since 1929; many companies are anxious to keep their workers until they are of retirement age, usually 65, and so the average age of the employee has increased. With increasing age, infirmities develop which make him unable to do the hard work to which he was adjusted to begin with. Then we assign him to a soft job. Those soft jobs have become saturated. We must in fairness to ourselves make labor understand that to protect those who have seniority with us we shall have to raise our standard of physical examinations somewhat, because each time we take in a new employee who becomes a problem early and of whom we have to take special care, we don't lay him off. We are beginning to have to do that at the expense of somebody older in seniority. It is a good deal a case of promotion by demerit, because the softer jobs are easier. The night shift jobs are usually day jobs carrying less physical work and probably a little more responsibility, so they are preferred. If we do not maintain a reasonably adequate standard of physical health, we are doing an injustice to the older employees.

DR. STANLEY J. SEEGER, Milwaukee: In order to put credit where credit is due, I wish to say that the so-called Wisconsin plan presented to you today is the plan of the Wisconsin State Industrial Commission. It was conceived by that commission and was brought to its present state of perfection by the commission. The commission deserves credit for its broad vision of social problems and of medical problems in the development of this plan. I should like to disclaim any credit at this time for the development of this excellent plan. In the second place, to make clear the matters with which the council has concerned itself I would say that probably 85 per cent of the industrial population of this country is cared for by the general practitioner, who has a relatively casual or, in some instances, a rather specialized interest in the problems of industry. That figure of 85 per cent may be high, but it can be vouched for in some studies, at any rate. We are not so immediately concerned with the level of physical examination in some of the ideally organized, large industries. We all know that problems exist there which are being studied by men spending their full time on work in these industries and who are giving these problems serious attention. In response to one of the discussers, it is the attitude of the council that we do not criticize the work of the leaders in this field. We do not fear for the future of the private practice of medicine because of the activities of men who represent the best in this field, and I think you will find we are on record to that effect. The problem which is arising and which is defining itself very rapidly is How are we going to extend the benefits of physical examination to the small industry which is now being cared for by the general practicing physician? We have brought this problem before you and have suggested means of organization within county and state medical organizations, so that the practicing physician may meet these problems. He must make certain concessions regarding the special nature of x-ray examinations, for instance, and must work out certain economic difficulties. I believe it can be done. I am not one who laments the fact that the general practitioner is not going to be competent to do physical examinations in industry or that his instrumentalities of organization are not competent to meet the problem of public health which is being put before him. I think the practicing physician must be made aware of what is going on in the minds of public health workers and of industrial physicians and surgeons in this regard. On the other hand, there is great need for public health workers to understand what is going on in medical organizations and to utilize the instrumentalities of county medical societies in the furtherance of their work. If this is public health work, I think we must all accept the principle, which has been stated so often by public health workers, that no public health enterprise can be carried to its logical conclusion without the aid of the practicing physician.

JANUARY 16—AFTERNOON

DR. C. W. ROBERTS, Atlanta, Ga., in the Chair

DISABILITY EVALUATION

Hearing Loss: Estimation of Disability

DR. AUSTIN HAYDEN, Chicago: Hearing has been enormously extended in the past sixty-five years since Alexander Graham Bell invented the telephone. With about 40 million telephones and 100 million radio receiving sets, the human voice can be heard all over the earth. In addition, electric recording preserves sound, so that our voices can be transcribed for reproduction to future generations. In spite of all that, the Illinois Industrial Commission did not until 1929 take any note of compensation for industrial hearing loss. For the total and permanent loss of the hearing of one ear in 1929, 50 per cent of the average weekly wage during fifty weeks and for the total and permanent loss of hearing in both ears 50 per cent of the average weekly wage during 125 weeks was set up. While the compensation for industrial hearing loss, as decided by the Illinois Industrial Commission, is infrequent and small, in civil suits the amounts are sometimes considerable.

I believe that proper standards for compensation and the accurate determination of disability following hearing loss had better be set up by organizations of this kind rather than haphazardly by socially inclined partisan groups. Employees, employer and the public are entitled, I believe, to the real facts about hearing and hearing disability. To ascertain these, hearing must be a definite part of a general physical examination at the beginning of employment, similar to vision. It must be part of subsequent examinations. Hearing must be a definite part of examination after injuries, especially on the head, and hearing expectation in certain employment must be carefully computed. In addition, the fact that hearing deteriorates with age, just as vision does, must be taken into account, and the word "presbycusis" instead of "presbyopia" is probably applicable. Older methods of hearing examination by voice, tuning forks, watches and so forth are no longer adequate. Audiograms are required. Individual tests of each ear separately are essential. They should be qualitative for sound frequency and quantitative (in decibels) for sound intensity, with a continuous frequency fundamental tone audiometer, calibrated at octaves as well as octave letters. They should be performed by or under the immediate supervision of an otologist, throughout the hearing range from auditory to pain thresholds, by both bone and air conduction, in a quiet testing room. Audiograms can be made rapidly, except for the very hard of hearing, and should include otologic history and complete ear examinations with investigation of vertigo when indicated. They are essential for the prescription of modern hearing aids, as well as for the determination of the unpredictable factors that are so common to hearing loss.

This slide shows an audiogram. The Council on Physical Therapy of the American Medical Association, through its Committee on Hearing Aids and Audiometers, is trying to get a standard audiogram to present to industrial men that will be readable and understandable throughout the entire country. We invite you to use that audiogram just as soon as it is ready.

Audiograms should be made on letter size paper for ease of filing. Audiograms may be filed as this slide shows, using a line for the whole chart and the dates at the side to study the progress of the otologic patient.

This slide shows the audiometer itself. Hearing is measured through the most useful part of the hearing scale, that is, from 128 to 8,192 cycles per second. That doesn't mean the entire range of human hearing, which would go from 20 to 20,000 cycles. The audiometer should be used in a quiet room, in a sound-proof room if possible. A room that registered 20 and not more than 30 decibels of sound would be advisable, and many offices can be made into such rooms at a small expense.

This slide shows an instrument that corresponds to the trial frame in ophthalmology. From the measurements that are made with the audiometer, the hearing curve is charted on the audiogram, and the defects in that hearing curve, the up and down steps or the even slopes of hearing loss can be fitted by

this audioscope. By its use the actual variations in sound amplification that the audiogram indicates should go into the patient's hearing aid and can be actually tried by the patient, just as glasses are tried in the trial frame for the correction of visual defects.

In every audiogram there are four lines, two for air conduction, which are generally indicated by unbroken lines, and two for bone conduction, which can be indicated by broken lines.

The individual shown in this slide is quite hard of hearing. He would hear by air conduction probably at 4 or 5 feet, but his bone conduction, which is an index of the condition of his auditory nerve, is way up at the top. He can be fitted splendidly with a bone conduction hearing aid, and his hearing can be brought clear up to the top, can be improved from about 20 feet up to about 4 feet by air conduction.

This slide represents a so-called middle ear or obstructive lesion. There are still four lines there. The bone conduction has come down, the air conduction isn't so bad, but all the lines are closer together, and that represents a mixed perceptual chart that is difficult to fit. You can't tell by looking at the chart definitely whether bone or air should be used, and it is not as favorable as the first one.

Now we have done something about seeing how much correction is necessary. We can tell by using the whisper test how much improvement a hearing aid gives. We can also place the receiver of the audiometer on the transmitter of the hearing aid and make an audiogram of the hearing aid. It is in these cases that the operation of hearing windows, so widely publicized within the last year, has been advised. In no case of which I have seen a record does the improvement after that six hour operation equal the improvement with a properly fitted hearing aid; and whatever the improvement is, the length of time that has elapsed since operation is not sufficient to assure that the improvement will be permanent.

An air conduction loss of 30 or 40 decibels would give hearing of 4 to 6 feet and would be improvable up to 12 to 16 feet by an air conduction receiver.

With the bone conduction, the results are startling. With a loss of 10 decibels by bone conduction, which might be 60 or 70 with air conduction, which might be a hearing distance of only 3 or 4 feet, you can get 20 to 30 feet, and so on down.

The decibel is something that does not submit itself to percentage calculation. For instance, one's heart beat is estimated to be 10 decibels loud. The threshold of pain is said to be 130. It is estimated that way on the audiogram I showed, but 130 doesn't mean 10 times 13 at all. It means 10 trillion times 10, so that the amount of the energy of 10 decibels going in here is increased beyond any calculation in percentage.

This slide shows the multiple parts that are available for hearing aids today. When you see that this transmitter can be combined with this receiver, this amplifier with this ear tip, this battery with any of those, you can readily understand that many hundreds of hearing aids, each one different from the other, can be made. What is the use of so many? It is just like cylinders and spheres in glasses. The irregularities of hearing loss call for amplification at many certain spots in the audiogram and that is accomplished by the use of these variously pitched parts together with the use of filament.

The Committee of Consultants on Audiometers and Hearing Aids of the American Medical Association, Council on Physical Therapy, is standardizing equipment and methods, so that clinical data can be universally interpreted and evaluations of function and loss of function accepted, as has been so well done in ophthalmology. Courts and compensation boards are demanding the same of otolaryngology.

The first audiometer for general clinical use met Council requirements less than three months ago. With the incomparable resources for clinical investigation that American industry provides in its splendid corps of physicians and surgeons, speaking through their Council on Industrial Health of the American Medical Association, cooperation between these two councils will greatly facilitate, for the benefit of all concerned, the accurate estimation in hearing loss quickly, accurately and justly.

Present Status of Estimating Disability from Visual Loss

DR. HARRY S. GRADLE, Chicago: Central visual acuity has been measured by means of the Snellen chart for a century or more, and the results of the Snellen chart are expressed in the form of what appears to be an ordinary fraction. Snellen never intended that to be a fraction; he intended that to be merely an expression in which the numerator was the distance at which the chart should be read and the denominator was the distance at which the chart actually was read. In other words, a vision of 20/20 means that the standard size chart, which should be read at 20 feet, was read at 20, whereas 20/40 means that at 20 feet the individual could only read that chart which should have been read at 40. The expression 20/40 does not mean a loss of 50 per cent of visual acuity. The thing you are to understand is that this was an expression and not a ratio, not a fraction, that led to the confusion. So the committee that was appointed by the Section on Ophthalmology of the American Medical Association in 1919 had to start practically from the ground up.

In the past, estimations had been made on the loss of visual acuity in the injured eye only, based on a percentage of the loss of the total eye. In other words, where one state allows fifty weeks' salary for loss of a total eye, the estimations had been that, if there was 20/40 vision, 50 per cent of that had been lost.

We started on an entirely different basis. We worked out a table which has been widely accepted by the compensation boards of the various states and by many large insurance companies. I thought, for your benefit, we might take this table to pieces today and analyze it and simplify the explanation. The committee started out by estimating how much the efficiency of the individual was decreased by the resultant loss of visual efficiency. We took as the base line from which to work complete total disability of the individual and said that complete loss of visual efficiency is equivalent to the total permanent disability of both eyes and is identical with total permanent disability of the individual. Then it simply is a matter of determining the visual efficiency, and we for the first time took into consideration the efficiency not only of the injured eye but of the uninjured eye as well.

The efficiency of any eye is a question of several factors. The first factor is, of course, the central visual efficiency for distance. The central visual efficiency for distance is measured by the Snellen chart, that is, the ability to recognize letters at an angle of 5 minutes. That is known as 20/20. We accepted the Snellen standard of measurement of central visual acuity at 20 feet under illumination of not less than 3 or more than 10 foot candles. For normal, or 100, 20/20 has been universally accepted by ophthalmologists from time immemorial.

What was the zero line? Total blindness is absolute zero, and it was impossible to estimate the exact evaluation of total blindness. After experimental work, we found that 20/800 represented the maximum loss that could be measured. In other words, if a man could see at 20 feet only such characters as he should be able to recognize at 800 feet, he was practically blind. Therefore we accepted 20/800 as a 99.9 per cent loss in central visual acuity.

The next factor that had to be considered was the visual acuity for near. In the past, they have taken into consideration only vision for distance. That is all right for a man who is working as a common day laborer, but a man who is doing fine work, near, may have comparatively useful distant vision but his near vision would be hopelessly destroyed so that his efficiency would be lost. That necessitated, on the part of the committee, a complete evaluation of vision for near, and we accepted the standard reading distance of 14 inches and on that basis worked out a similar table, where central visual acuity for near is also taken into consideration and measured. We must take into account also the visual field of that eye. The average ophthalmologist does not have the graduated chart for near. Therefore it became necessary to develop this chart, which was published in a later issue of THE JOURNAL.

We have here the Snellen notations at 14 inches based on the American Medical Association table and, correspondingly,

in the diopter or metric system, or on the Jaeger No. 1 system, the size of the letters, the visual angle, and the percentage of visual loss. That figures out exactly as does the visual acuity for distance.

The next factor which must be considered for visual efficiency for one eye is the visual field. There are many disabling effects that cause a decrease in the visual field, so we accepted the standard field, as shown in the perimeter, in which the field is plotted in the eight principal meridians. In measuring visual efficiency of each eye, the visual field must be taken in the eight principal meridians. The amount of field that persists in each meridian is then added together and divided by 420, which gives the total visual field efficiency of that eye in percentage.

So the extent of the field of vision shall be determined by the use of the usual perimetric test methods, a white target being employed which subtends a 1 degree angle under illumination of not less than 3 foot candles, and the result plotted on the industrial visual field chart.

The amount of radial contraction in the eight principal meridians shall be determined. The sum of these eight, divided by 420 (the sum of the eight principal radii of the industrial visual field) will give the visual field efficiency of one eye in percentage.

There is one more factor that must be taken into consideration in determining the visual efficiency, namely the motor ability of that eye. If one eye is disabled so that it cannot move simultaneously with the other, there will result double vision. Therefore it is necessary first to measure and then to plot out the motor function of each eye. When diplopia is present, this shall be plotted on the industrial motor field chart. This chart consists of twenty rectangles, representing the motor field area of the two eyes in question. If diplopia is present, we must test for it at 1 meter with a red light and a candle in each one of these twenty areas, and from the results there is evaluated a definite loss in motor function according to the number of areas in the rectangle in which diplopia exists. In other words, if there is no diplopia there is 100 per cent motor function, whereas if diplopia exists in all twenty fields there is complete loss of motor function.

Now we have the factors that are concerned in the development of industrial visual efficiency of the eye. How shall we evaluate? They are not all of equal value. First, we work out the central visual acuity efficiency. In doing so we take the visual acuity for distance and give to the visual acuity for near a twofold value. In other words, near vision is practically twice as valuable to the industrial laborer as is distant vision. In order thus to attain the central visual acuity efficiency, we take the value of the central visual acuity for distance, to which is added twice the value of the central visual acuity for near, all divided by three. This gives us the central visual acuity efficiency of the eye, taking into consideration the vision for distance and the vision for near, and laying weighted value on them.

For the visual efficiency of the eye we have to multiply the central visual acuity efficiency by the visual field efficiency, the muscle function efficiency. In other words, the central vision, which is composed of distant vision and near vision, times the efficiency of the eye as regards the visual field, times the motor efficiency of the eye, gives us the visual efficiency of the eye in question. That is done to both eyes, but here too there is a weighted value to be given. Perhaps it can be put down in this form. The first calculation is the central visual acuity for distance plus two times the central visual acuity for near, which gives the visual acuity efficiency of one eye. Then the visual acuity efficiency times the muscle function, times the visual field efficiency, gives the result of the visual efficiency of one eye. The injured eye may be the better eye of the two. Consequently we do not speak of the injured eye or the uninjured eye but we speak of the more efficient eye and the less efficient eye.

To obtain the visual efficiency of the individual we take the visual efficiency of the less efficient eye, no matter whether it is the injured or the uninjured eye, and add to that three times the visual efficiency of the more efficient eye, and that divided by four gives the visual efficiency of the individual. If we

have visual efficiency of the individual in terms of percentage, subtracting that from 100 per cent gives us the amount of loss of efficiency of the individual, basing that on the complete disability of the person as a whole. All through the pamphlet are given various illustrations to show how it works out.

On page 10 is the authorization. This report, as published by the Committee on Compensation and adopted by the Section on Ophthalmology, was adopted by the House of Delegates in 1925. It then became the official report of the American Medical Association on the estimation of appraisal of loss of visual efficiency subsequent to injury.

Let me call attention to paragraph 2, page 4, probably the most troublesome aspect. If a man has a traumatic cataract, that cataract is either absorbed or operated on, and there results with the proper correcting glass 100 per cent central visual acuity for distance and for near, to what is that man entitled? It is impossible for him to wear the glass over the affected eye and use that eye and the uninjured eye simultaneously because of the size and image of the two eyes. Is he entitled to compensation for the loss of an eye because he cannot use the two eyes simultaneously? On the other hand, if the other eye was injured he still would have the perfect eye to fall back on. Therefore the committee decided that, if there is a greater difference than 4 diopters of spherical correction between the two eyes, the best vision that can be obtained with not more than 4 diopters difference in glasses shall be that which is used. It works out practically that if the uninjured eye is normal and the injured eye necessitates glasses for correction, the individual obtains about 75 per cent of the compensation that will be awarded for the complete loss of an eye. Probably that is the fairest plan that could be made.

There are certain types of ocular disturbances which are beyond possible estimation: disturbances of light and dark, various deformities of the lid resulting from scar tissue, muscle disturbances that are not included under diplopia, and things of that sort which have been worked out, each one on its own basis. There can be no mathematical appraisal of such losses. One should not be in too big a hurry to estimate a visual loss. We believe that at least four months should elapse from the time of injury before the examination is concluded on which the appraisal is to be based. We also recognize that in the course of time certain improvements will occur, but it is impossible to drag the time out too long. Therefore twelve months is the maximum time that should be allowed to elapse before the examination is made.

This is an extremely simple table, which merely requires a little understanding of the analysis. If you figure again the analysis that is based on each eye individually, realizing that the analysis of each eye is based merely on visual acuity for distance, visual acuity for near, visual field and motor function and put them into the formula in which the weighted values occur, you will have no difficulty in estimating the percentage of complete disability of the individual that may result from injury to one or to both eyes.

Presentation of Dr. Ludwig Teleky

Dr. Ludwig Teleky, lately of Vienna, was introduced by Dr. Robert T. Legge, of Berkeley, Calif.

DR. LUDWIG TELEKY, lately of Vienna: I am happy to be in this beautiful country, and not only that I can be here but that I can work here. It is very odd for me to work in a country which has so many scientists in my field and who have done so much good work. So I came here to learn and to see the work which has been done by your scientists.

Are Uniform Standards of Evaluation Practicable?

DR. EARL D. MCBRIDE, Oklahoma City: The physician called on to assist in the cause of justice by rendering expert testimony is of value to the side of the case employing his services or else he is not called to testify. The testifying physician must conduct himself according to the rules of the court. He cannot elect to relate and explain his observations and opinions in his own manner. Questions are cleverly designed to elicit desirable answers. The clinical data are twisted to meet a given situation. Scientific deductions are discredited by sly inference. Facts are distorted to meet a theory of the case.

Hypothetical questions are propounded to fortify or impeach evidence. The scientific background of the medically trained mind does not conform well to the legal methods of arriving at conclusions of fact. Proof of reality in the development of scientific facts is accomplished through systematic research. Facts to be proved are based on a chain of reasoning directed by facts already established. The scientific minded physician dislikes decisions involving a monetary issue and recoils from any action which may trespass on the scientific spirit.

In view of this situation I should say that uniform standards of evaluating disability are practicable but certain adjustments will be necessary before they can be suitable for recognition by either the courts or the medical profession:

First, the judiciary must remedy the system which permits inconsistencies due to partiality in the scientific presentations of medical experts.

Second, the medical schools must improve the curriculum of medicolegal instruction to train the student how to meet judicial inquiries with the same degree of confidence expected of him in diagnosing disease or in consulting with others of his own profession.

Two adjustments which would be beneficial on the part of the judiciary are:

1. Doctors called as medical witnesses on opposite sides of the case should be permitted to consult and to compare and present their observations and diagnostic opinions with the same degree of serious, scientific intent as is expected of them in the practice of medicine.

2. Prestige of a specialist should be acknowledged by the court as rated by medical bodies and boards established for the purpose of standardization. The qualifications admitted only by the doctor as he takes the stand should not be relied on.

The medical profession could make the following adjustments:

1. Medical bodies governing actions of their individual constituents could adopt standard rules and regulations covering qualifying standards and professional behavior of the doctor in court.

2. Medical associations of national scope might prepare and adopt certain fundamental principles of medical standards in evaluation of personal injury and permanent disability.

When such adjustments are accomplished, standards for evaluating disability will be not only practicable but authoritative. There will be more confidence in the testimony of medical experts.

The problem of setting up such standards is a pressing issue. Arbitrary ratings and pension payments have been set up by law that seem to meet the need in a number of situations; however, it will never be possible through medical analysis to tabulate or grade equitable evaluations of permanent disability by dogmatic scale. As doctors we cannot tabulate percentages of disability common to all forms of physical alterations of the body and expect to establish an adequate schedule that will meet individual circumstances of working capacity. For years I have attempted to point out that the medical examiner should confine himself to his field of knowledge and experience when determining percentages of disability. This method of arriving at a conclusion should be as scientific as that of arriving at a diagnosis in human illness. The doctor is actually not competent to evaluate disability with respect to manual labor or specific vocations because he is not trained to know their technical requirements. He is competent, however, to determine the extent of loss of use of a part of a man's body as compared with the normal. Therefore, as a basis of procedure in evaluating permanent disability I have recommended that we rely on the determination of the extent of function of the body or parts of the body as they are affected by disability. Such a determination falls conclusively within the field of medical practice. Function, or the ability to perform useful activity, is one standard unit of measurement which can be used authoritatively by the medical expert in his disability appraisal and the court may then arbitrate loss of earning capacity and adjust monetary awards.

A practicable formula is established by integrating function into seven component factors, each of which is given a percentage value in its relation to 100 per cent. These factors and their relative percentages of value are designated as

follows: (1) quickness of action, 10 per cent; (2) coordination of movement, 20 per cent; (3) strength, 20 per cent; (4) security, 10 per cent; (5) endurance, 20 per cent; (6) safety as a workman, 10 per cent; (7) prestige of normal physique, 10 per cent. Much more could be said on this subject, which would require a volume to contain the technical details contributing to the successful use of the formula presented. Uniform standards of evaluation of disability are practical. The true medical status of disability is not under the prevailing system.

The Evaluation of Disability Following Industrial Accidents

DR. HENRY H. KESSLER, Newark, N. J.: The extent of bodily injury has been used in arriving at an evaluation of reduced earning ability. Theoretically this method is fundamentally incorrect, for it is not the lesion that is to be indemnified but the effects of that lesion on the earning capacity of the injured person. A similar lesion in different individuals may not have the same effect. Age, sex, occupation, social condition, economic stress and opportunity for employment may have an important bearing on the ultimate loss in earnings of an injured workman.

There is no system of pathology through which the capacity to work can be clearly determined. Nevertheless society has forced the physician to derive a social judgment from pathology. A man lame in two legs may be fully capable of work, while a neurotic person may be completely incapacitated. This produces an inconsistency and conflict that is frequently found between the pathology of defect and the economy of working capacity. While lead poisoning and spondylitis are medical illnesses, incapacity to work is a social illness.

It may be readily seen why there is so much discrepancy in the estimates made by several physicians in the same case. This is not the result of lack of honesty in the examining physicians as much as the lack of a common ground on which to meet. Moorhead, in rating permanent disability after fractures, suggested that three factors be taken into account: the anatomic result, the functional result and the cosmetic defect. McBride has suggested the use of seven psychophysical traits as arbitrary criteria for estimating disability. Since the range of human capacities is limitless it would be fallacious to select these traits to the exclusion of others. The method of ascribing fixed values to each factor and the method of determining each value is left to the opinion of the examiner. No attempt is made to measure actually the degree of impairment of the individual trait.

I have recommended the use of function as a criterion for the evaluation of permanent disability. I have defined function as it applies to the extremities, as motion of the joints, power of the muscles and coordination and control from the brain through the peripheral nerves. I have further described a detailed technic for the actual measurement of these qualitative components of physiologic function.

General tests of bodily function or efficiency have been used by many. The pulse rate and blood pressure are taken before and after exercise and compared with arbitrary normals; in addition, specific functional tests have been developed for the extremities and for vital organs. All these tests, however, are false; first, because they do not evaluate the total body but select and abstract only a small part of it; second, because of the mechanical fallacy.

Physicians, as well as laymen, frequently commit the error of undervaluing the individual's capacity to work. It is often assumed that a physical defect causes limitation of functional activity and hence limitation of industrial usefulness. This line of reasoning is frequently invalid. While it must be conceded that the disability may limit the number of opportunities open to the disabled person, it is far from correct to assume that a physical disability always means incapacity to work. Regardless of the yardstick used, the judgment is apt to be erroneous. This is due to the ever present psychic component and to the presence of the safety factor.

The case histories of 4,404 men with permanent orthopedic disabilities, covering a period of thirteen years, were exam-

ined by Anderson, and the actual jobs they had held for that period of time were listed. The data indicated that among 10,176 jobs held by these men there were 635 different types of work, representing 70 per cent of the 557 occupations and occupational groups listed in the United States census of 1930. These figures give striking evidence of the versatility of these handicapped men. How do these physically disabled persons manage to make their physiologic adjustments? How do they accommodate themselves to the unusual demands made by disease or by congenital or acquired defects? The answer will depend on the presence of human safety factors and personality adjustment.

A person can get along with one third of a kidney or one fourth of a liver, without a stomach, without a large intestine, with one tenth of the pancreas, with one third of the thyroid, with one fourth of the parathyroid, with one tenth of an adrenal, with one tenth of an ovary, with one half of the total volume of blood and with 20 per cent hemoglobin. There is also a factor of safety in the ability to substitute one foodstuff for another.

Personality maladjustment plays an even more important role in the causation of incapacity to work than the physical deformity. It may be so great as to suppress the individual completely.

We are faced with this practical problem of assisting the industrial commission in the rating of permanent disability. The problem can be solved in two ways: A method which I rely on is the use of an actual work demonstration on the part of the patient. This method was carried out through the use of a curative workshop consisting of a complete woodwork and paint shop and all the tools used in carpentry and cabinet making with the exception of automatic machinery. There is a weaving department with two looms, where rugs and other articles are woven, and a fairly complete print shop, with type cases, press and other equipment. Here the injured person or the convalescent is gradually adjusted back to employment conditions without overtaxing his physical resources. Here the man with lowered morale and lost confidence has an opportunity to establish himself under favorable and sympathetic auspices yet with a mild discipline that develops his morale. The work shop has been in operation fourteen years and it has demonstrated its value as a therapeutic agency by rehabilitating badly disabled persons in difficult cases and by serving as a laboratory for determining work capacity and employability.

On the basis of an actual demonstration of work the patients are arbitrarily divided into three groups: those who are non-productive, those who show a fair productiveness and those who are very productive. Arbitrary estimates of disability are allotted as follows: 60 to 100 per cent for the nonproductive group, 33 to 50 per cent for those showing fair productiveness and 0 to 10 per cent for the very productive group. The second method is the adoption of schedules or principles of evaluations proposed by representative medical bodies. The work of the Section on Ophthalmology of the American Medical Association is an excellent example of such a contribution. The suggestions of the Council on Physical Therapy with respect to audiometer tests of hearing defects is a further illustration. In European compensation practice, schedules and methods of evaluation submitted by private physicians not associated with the official administrative agency are frequently given official approval and are utilized in making determination. The tables of Liniger and Molinex in Germany and those of Sachet, Imbert, Forgue and Jeanbrau are examples of this procedure.

DISCUSSION ON DISABILITY EVALUATION

DR. W. P. WHERRY, Omaha: I am here only as an observer, representing one of the larger special societies, but in that capacity I do appreciate the necessity for what Dr. Kessler called dictatorial standards. I admit that variables must always enter into a medical evaluation of a defect. It is the medical man who must estimate the variables. However, when compensation and disability are discussed in terms of dollars, there are other professions that ask assistance along mathematical lines, more or less, and medicine must adjust itself to setting up base lines, a common ground, whether it is a matter of hearing,

vision or functional defects of workable parts of the human body. From that basis we perhaps shall have more of an acceptance in court in compensation adjustments than if everything is left to the whims of a medical mind. One thing that has been said against medicine is that six expert witnesses in hearing defect cases will none of them agree. I think it is the expression of many lawyers that a medical witness is used for the effect on the jury rather than for the acceptable factual data. That is a travesty on medicine. One of the objectives of the specialty which I represent is not to put matters on the basis of an exact science, because when anything becomes an exact science it ceases to be a science; but I also feel that with a common base line medicine will have a better acceptance. Much of this economic pressure has been brought on medicine because of the high cost of poor medicine, not the high cost of good medicine, and I can't help but feel that in the evaluation of defect problems poor judgment can sometimes be put in the same category with poor medicine.

QUESTION: I should like to ask Dr. Hayden what type of intensity of noise he regards as damaging to workmen's ears, and the best type of protection to afford him against such damage.

DR. AUSTIN HAYDEN, Chicago: That depends on the constancy of the noise and on sudden or temporary increases of noise, as, for instance, in a plant where explosives are used to blow food out of reservoirs. We made some studies and found that the workers in a plant of that sort had a very considerable loss of hearing in the upper tone scale. Prevention means many things that many workers don't like to do. If they use plugs of cotton or wool or other material in the external auditory canal, the jar through the bones of the skull may be a factor even though the canal is closed. The changes begin, both in war and in such occupations as I have mentioned, in the upper tone scale. Not enough work has been done yet to determine whether that can be prevented or not. The same is true of boiler-makers' disease and may be true of caisson workers. A suggestion has been made that perhaps the best individual to put into a noisy occupation is one who is hereditarily disposed to chronic loss of hearing. That is to say, if he has a strong history of otosclerosis, maybe he is the fellow that ought to go into that work because his ears are going to get bad anyway. That has been proposed by the United States Public Health Service, and it has some merit.

DR. EARL D. MCBRIDE, Oklahoma City: The point I was making in my paper is that if we have a formula, something to go by after we have done all of our examination, after we have used our measuring apparatus and made our tests, as Dr. Kessler suggests, we can analyze the results according to that formula. I have tried it with several different individuals, when we had a claimant's attorney, a company attorney, a commissioner and myself, and we weren't 5 per cent apart when we asked ourselves the same questions through that same formula. If we can hit on something that will give us a uniform method of reasoning, then I feel we shall not be far wrong when we come into the industrial court with these disabilities.

DR. H. H. KESSLER, Newark, N. J.: I think Dr. McBride has emphasized the important point, the question of agreement on certain bases and formulas. There is one other point and that is the notion that so many differences exist between individuals. If you carefully scrutinize the studies that have been made with respect to the actual traits in human capacities in all individuals that have been carefully measured, you will find those differences not as great as you think them. It is remarkable, but you will find that rarely does the efficiency, the productivity or the dexterity of one individual exceed by more than twice that of the less efficient individual. I mention that because so much emphasis has been made on these minor physical defects. I think this emphasis is due not so much to a rational, scientific appreciation of their importance as to a peculiar emotional factor. This emotional factor is tabu. Actual studies of accident proneness in handicapped persons have revealed that the accident proneness of such an individual is somewhat less than that of the normal group.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 685 has passed the House, proposing to create a Bureau of Water Pollution Control in the United States Public Health Service. Before the bill was passed, the House accepted an amendment proposed by the House Committee on Rivers and Harbors striking from the bill the provisions proposing federal grants-in-aid to assist states, municipalities and public bodies to construct treatment works to prevent pollution of navigable waters and substituting therefor an authorization whereby the Reconstruction Finance Corporation may make loans to finance the construction of treatment works. S. 2284 has passed the Senate and House authorizing the President to appoint in the navy 100 acting assistant surgeons for temporary service.

Bills Introduced.—S. 3461, introduced by Senator Murray, Montana, and H. R. 8730, introduced by Representative Keller, Illinois, propose to provide for the general welfare by enabling the several states to make more adequate provisions for the control and prevention of industrial conditions hazardous to the health of employees. These bills contemplate that there shall be appropriated for the fiscal year ending June 30, 1941, the sum of \$1,000,000; for the fiscal year ending June 30, 1942, the sum of \$2,000,000; for the fiscal year ending June 30, 1943, the sum of \$3,000,000, and thereafter such sums as may be necessary to carry out the provisions of the act. Such amounts, it is proposed, will be allotted to such of the several states as have submitted plans acceptable to the Secretary of Labor. A plan may not be approved by the Secretary of Labor unless it provides for its administration by the state labor department or other agency charged with the administration of the general labor laws of the state or under their supervision; provides for compulsory reporting by employers to the state agency charged with the administration of the plan of all cases of disability or death due to any disease caused, accompanied or aggravated by exposure to conditions of employment hazardous to health; provides for an industrial hygiene agency to develop and appraise methods of controlling industrial conditions hazardous to the health of workers, and provides that the state agency or agencies administering the plan will make such reports, in such form and containing such information as the Secretary of Labor may from time to time require and comply with such provisions as the Secretary of Labor may from time to time find necessary to insure the correctness and verification of such reports. The Senate bill is pending in the Senate Committee on Education and Labor, the House bill in the House Committee on Labor. S. 3435, introduced by Senator Reynolds, North Carolina, proposes to provide for domiciliary care and medical and hospital treatment for former members of the military and naval services who are suffering with tuberculosis. H. R. 8672, introduced by Representative Lenke, North Dakota, proposes to prohibit the use, sale, purchase or exchange of any seal, stamp or certificate of another person, association, organization or company denoting or implying equality or superiority in purity, quality, usefulness or effectiveness of any drug, food, cosmetic, therapeutic lotion, therapeutic device or diagnostic or surgical assists in comparison or competition with other products of like kind, or similar nature, unless, such seal, stamp or certificate has been approved by the Federal Trade Commission. H. R. 8695, introduced by Representative Tolan, California, proposes to provide grants to the states for assistance in the rehabilitation of disabled persons incapacitated for normal employment. H. R. 8696, introduced by Representative Tolan, California, proposes federal grants to assist states to provide money payments to needy individuals who are 18 years or more of age and who are totally and permanently disabled and incapable of self support by reason of physical defect or impairment of the body, other than the mind. H. R. 8765, introduced by Representative Pearson, Tennessee, proposes to provide for free hospitalization and medical attention for all veterans of the World War and the Spanish-American War in government facilities. H. R. 8794, introduced by Representative Thill, Wisconsin, proposes to permit federal income tax payers to deduct amounts actually

paid during the taxable year for medical, dental, surgical or nursing treatment or hospitalization of the taxpayer or his spouse or any dependent for whom a credit is allowable. H. R. 8800, introduced by Representative Tolan, California, proposes to amend the Social Security Act so as to provide benefits for persons physically disabled to such a degree that they are not capable of self support.

DISTRICT OF COLUMBIA

Bills Introduced.—H. R. 8670, introduced, by request, by Representative Bolles, Wisconsin, proposes to establish a Board of Funeral Directors and Embalmers for the District of Columbia. H. R. 8692, introduced by Representative Randolph, West Virginia, proposes to enact a new podiatry act for the District of Columbia. Under the provisions of the bill any person is to be regarded as practicing podiatry who furnishes, or advertises to furnish, podiatry service or performs or causes to be performed podiatric operations of any kind, diagnoses, or professes to diagnose, prescribes for or treats or professes to treat disease, pain, deformity, deficiency, injury or physical condition of human feet or adjacent structures. Among the subjects on which applicants are to be examined are pathology, materia medica, surgery, and clinical and orthopedic podiatry.

STATE MEDICAL LEGISLATION

Kentucky

Bills Introduced.—H. 532 proposes to appropriate \$150,000 for the establishment of a state tuberculosis sanatorium in Johnson County, to be under the control and supervision of the department of welfare. H. 539 proposes a procedure whereby hospitals may be reimbursed by the state for the expense of caring for indigent persons injured in motor vehicle accidents.

Bill Introduced.—H. 534, to amend the uniform narcotic drug act, proposes to define narcotic drugs so as to include cannabis.

Mississippi

Bill Introduced.—H. 552 proposes to authorize boards of supervisors of the several counties to levy, in addition to the levy for indigent sick, a special tax of not exceeding 1 mill on all the taxable property of the county, to provide necessary medical, dental or other treatment to children up to 16 years of age in need of and unable to procure the services and treatment referred to.

New York

Bills Introduced.—S. 1348 proposes that an applicant for a license to operate a motor vehicle must be examined by a physician at least once every three years and be certified to as physically fit to drive a motor vehicle. S. 1351 proposes that on the trial of any action arising out of acts alleged to have been committed by any person arrested for operating a motor vehicle while intoxicated, the court may admit evidence of the amount of alcohol in the defendant's blood, the test for which must be taken within two hours of the time of the arrest. Evidence that there was at that time 0.05 per cent or less by weight of alcohol in the blood is prima facie evidence that the defendant was not in an intoxicated condition sufficiently to lessen his driving ability. Evidence as to the presence of from 0.05 per cent to 0.15 per cent is relevant evidence but is not to be given prima facie effect in indicating the ability of the driver to operate the vehicle. Evidence as to 0.15 per cent, or more, is prima facie evidence that the defendant was in an intoxicated condition sufficiently to lessen his driving ability. S. 1395 proposes that the board of education of a city or school district maintaining vocational schools must provide health services for the pupils of such schools. The health service is to include the necessary personnel to afford adequate physical examination and is to include roentgenography of the chest of pupils. S. 1409, to amend the provisions of the workmen's compensation act requiring a physician attending an injured worker to make designated progress reports, proposes to require the physician to

submit a progress report every two weeks, or at more frequent intervals if requested by the industrial commissioner. No claim for medical or surgical treatment is to be enforceable unless the progress reports are made. S. 1412 and A. 1760, to amend the workmen's compensation act, proposes that an injured employee may, when care is required for an injury to the foot, select to treat him any podiatrist authorized by the industrial commissioner to render podiatry care. S. 1418 and A. 1761, to amend the provisions of the medical practice act relating to the practice of physiotherapy, proposes that a person who has practiced physiotherapy under a license granted prior to July 1, 1930, who on submission of proper credentials or by satisfactory examination has shown that he has received sufficient instructions and training, may be granted the right to practice physiotherapy without being required to do so under the supervision of a duly licensed physician, as the present law requires.

WOMAN'S AUXILIARY

WINNERS IN THE HYGEIA CONTEST

The American Medical Association offered \$300 in cash prizes to the state and county auxiliaries which obtained the largest number of subscription credits to *Hygeia*. The contest covered the period from Oct. 1, 1939, to Jan. 31, 1940.

Cash prizes were awarded as follows:

Group 1. Auxiliaries with a membership of from one to thirteen:

First prize, \$35, to Childress-Collingsworth-Hall counties, Texas, Mrs. S. H. Townsend, Hygeia chairman, Childress, Texas.

For the second prize, \$20, no county qualified.

For the third prize, \$10, no county qualified.

Group 2. Auxiliaries with a membership of from fourteen to twenty-three:

First prize, \$35, to Baldwin County, Ga., Mrs. H. D. Allen Sr., Hygeia chairman, Milledgeville, Ga.

Second prize, \$20, to Chelan County, Wash., Mrs. A. G. Young, Hygeia chairman, Wenatchee, Wash.

Third prize, \$10, to Clark County, Wash., Mrs. C. B. Hutt, Hygeia chairman, Vancouver, Wash.

Group 3. Auxiliaries with a membership of from twenty-four to forty-two:

First prize, \$35, to Vermilion County, Ill., Mrs. G. W. Walbright, Hygeia chairman, Danville, Ill.

Second prize, \$20, to Will-Grundy County, Ill., Mrs. D. W. Killinger, Hygeia chairman, Joliet, Ill.

Third prize, \$10, to Duval County, Fla., Mrs. Raymond H. King, Hygeia chairman, Jacksonville, Fla.

Group 4. Auxiliaries with a membership of from forty-three to 669:

First prize, \$35, to Buchanan County, Mo., Mrs. Charles H. Werner, Hygeia chairman, St. Joseph, Mo.

Second prize, \$20, to Lehigh County, Pa., Mrs. Henry D. Jordan, Hygeia chairman, Allentown, Pa.

Third prize, \$10, to Cook County, Ill., Mrs. E. M. Egan, Hygeia chairman, Chicago.

State winners:

First prize, \$25, to state of Washington, Mrs. J. B. Robertson, Hygeia chairman, Tacoma, Wash.

Second prize, \$15, to state of Illinois, Mrs. W. J. Wanninger, Hygeia chairman, Chicago.

Honorable Mention was given to the following county chairmen:

Kern County, Calif., Mrs. Eric Colby, chairman, Bakersfield.
Dallas-Guthrie County, Iowa, Mrs. E. J. Butterfield, chairman, Dallas Center.

Cape Girardeau County, Mo., Mrs. A. M. Estes, chairman, Jackson.

Virginia

Bills Introduced.—S. 284 proposes to enact a separate chiropractic practice act and to create an independent board of chiropractic examiners to examine and license applicants for licenses to practice chiropractic. The bill proposes to define chiropractic as "the philosophy, science and art of locating, any method preparatory to, and the adjustment of the articulation of the spinal column and adjacent bony structure to release the transmission of nerve energy to all parts of the body to correct the cause of disease." A licentiate is to be authorized to use such methods as are taught by chiropractic schools and colleges to further assist nature in establishing the normal transmission of nerve energy but is not to be entitled to use operative surgery, obstetrics, osteopathy nor to administer or prescribe any drug or medicine. H. 390 proposes to prohibit the operation of a maternity hospital unless licensed so to do by the state board of health.

Jackson County, Mo., Mrs. Ralph Myers, chairman, Kansas City.

LaFayette County, Mo., Mrs. C. T. Ryland, chairman, Lexington.

Lane County, Ore., Mrs. C. E. Hunt, chairman, Eugene.

Polk-Yamhill-Marion counties, Ore., Mrs. Burton A. Myers, chairman, Salem.

Fayette County, Pa., Mrs. John B. Hibbs, chairman, Uniontown.

Westmoreland County, Pa., Mrs. J. M. Mayhew, chairman, Greensburg.

Bowie-Miller County, Texas, Mrs. W. Decker Smith, chairman, Texarkana.

Salt Lake County, Utah, Mrs. Byron Rees, chairman, Salt Lake City.

Cowlitz County, Wash., Mrs. P. H. Henderson, chairman, Longview.

King County, Wash., Mrs. Hale Haven, chairman, Seattle.

Portage County, Wis., Mrs. Maurice G. Rice, chairman, Stevens Point.

Racine County, Wis., Mrs. F. B. Marek, chairman, Racine.

Sheboygan County, Wis., Mrs. A. J. Brickbauer, chairman, Plymouth.

Other counties that have reached or gone over their quota were:

Prairie County, Ark.; Arapahoe County, Colo.; Mesa County, Colo.; Bulloch-Evans-Chandler County, Ga.; Tift County, Ga.; Adams County, Ill.; St. Joseph County, Ind.; Dubuque County, Iowa; Cloud County, Kan.; Labette County, Kan.; Breathitt County, Ky.; Iberville Parish, La.; Washington Parish, La.; Washington County, Minn.; Alcorn County, Miss.; Omaha-Douglas County, Neb.; Cayuga County, N. Y.; Pottawatomie County, Okla.; Benton County, Ore.; Berks County, Pa.; Bucks County, Pa.; Huntingdon County, Pa.; Lebanon County, Pa.; Mifflin County, Pa.; Laurens County, S. C.; Hunt-Rockwall-Raines County, Texas; Kaufman County, Texas; Weber County, Utah; Kitsap County, Wash.; Pierce County, Wash.; Snohomish County, Wash.; Walla Walla County, Wash.; Whatcom County, Wash.; Kanawha County, W. Va.; Raleigh County, W. Va.; Rock County, Wis.; Washington-Ozaukee County, Wis.

The final result in this year's contest was 8,371 subscriptions, as against 6,242 received in the contest last year. The contest last year covered only the two months December 1938 and January 1939.

To the Hygeia chairmen, officers and members of the various county and state woman's auxiliaries who have assisted in making this contest a success, Mrs. Eben J. Carey, National Hygeia chairman, and the circulation manager of *Hygeia* express appreciation.

Medical News

MEDICAL NEWS

995

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Indian Service Hospital Closed.—The U. S. Indian Service Hospital at Fort Bidwell has been closed to patients. Owing to the extremely isolated location of the hospital, it has been found difficult to secure the continuous service of physicians. The personnel turnover has been unduly large and there have been many periods of time when no physician was available in the hospital by reason of lapses between assignments. The opening of Indian units at the Weimar Joint Sanatorium in Placer County and at the Wish-i-ah Sanatorium in Fresno County has made it possible to provide care for tuberculous Indians from northern California to better advantage than at the Fort Bidwell Hospital. General hospital care for the Indians in Modoc County will now be undertaken at local civil institutions. A generalized clinic and dispensary service under the charge of a full time Indian Service physician and public health nurse will be established at Alturas to provide dispensary care and public health services for the Indian population of the northeastern part of the state.

GEORGIA

University News.—Dr. Virgil P. W. Sydenstricker, professor of medicine, University of Georgia School of Medicine, Augusta, has been awarded a grant of \$6,000 by the Markle Foundation to continue his studies on pellagra.

District Meeting.—Among others, the speakers before the Sixth District Medical Society recently were Drs. Virgil P. W. Sydenstricker, Augusta, on "Conditions Associated with Deficiency of the B Group Vitamins" and David Henry Poer, Atlanta, "Use of Vitamin K as Preparation for Surgery in Common Duct Obstruction."

The Block Memorial Lecture.—Dr. Percival Bailey, professor of neurology and neurological surgery, University of Illinois College of Medicine, Chicago, will deliver the sixth annual E. Bates Block Memorial Lecture before the Fulton County Medical Society, Atlanta, March 18, on "Indications for Operations on Cases of Brain Tumor."

Society Honors Veteran Members.—At a recent meeting of the Fulton County Medical Society, Atlanta, certificates of honorary membership were presented to Drs. William L. Champion, Odom O. Fanning, John P. Kennedy, Pleasant L. Moon and Archibald Smith, Atlanta, and Michael Hoke, now of Beaufort, S. C. Certificates recognizing twenty-five years' membership in the society were presented to Drs. Thomas Blake Armstrong, William A. Arnold, Joseph Rex Barfield, Frank L. Eskridge, Henry Grady Estes, John B. Fitts, Harry N. Kraft, James Calhoun McDougall, Stephen C. Redd, Henry Clifford Sauls, Charles H. Paine, Atlanta; Kimsey E. Foster, College Park, and Chris H. Pinson, Hapeville.

ILLINOIS

Society News.—Dr. William Edward Chamberlain, Philadelphia, discussed "Pitfalls in X-Ray Diagnosis" before the Peoria City Medical Society on February 13.—Dr. Alfred J. Kobak, Chicago, discussed "Management of Prolonged Labor" before the Madison County Medical Society on February 2.—Dr. Leon Unger, Chicago, addressed the Macon County Medical Society in Decatur, January 30, on "Newer Phases of Migraine."—At a meeting of the Sangamon County Medical Society in Springfield, February 1, Dr. Lawrence S. Fallis, Detroit, discussed "The Technic of the Repair of Inguinal Hernia Including Fascial Transplants."

Chicago

Personal.—Dr. William H. Haines has been appointed assistant to Dr. Harry R. Hoffman, director of the Cook County Behavior Clinic. Dr. Haines is assistant clinical professor of neurology at Rush Medical College.

Society News.—Dr. Bela Schick, New York, will address the Chicago Society of Allergy, March 18, on "Allergy and Immunity."—A joint meeting of the Chicago Pediatric

Society and the Chicago Tuberculosis Society will be addressed, March 19, by Dr. Jay Arthur Myers, Minneapolis, on "Relationship of First Infection to Clinical Tuberculosis."—Dr. Frederic W. Bancroft, New York, will discuss "Traumatic Abdomen" before the Chicago Society of Industrial Medicine and Surgery, March 18.—Among others, Dr. Andrew F. M. deRoeth, Spokane, Wash., will speak on the "Hypofunction of the Lacrimal Gland" before the Chicago Ophthalmological Society, March 18.

Clinic on Necropsies.—An educational clinic, limited to members of the medical and funeral professions, will be held at the Stevens Hotel, March 19, under the auspices of the Chicago Medical Society, Institute of Medicine of Chicago, Chicago Pathological Society, Chicago Hospital Council, Cook County Hospital, Chicago Association of Embalmers, and Funeral Services Associated. The program will include motion pictures on the technic employed in the performance of a complete autopsy and subsequent restoration of the subject by embalming. Lectures on the social, legal and technical aspects of the technic of subsequent restoration by embalming by F. A. Cutler, director of research and education, National Selected Morticians.

Dr. Max Cutler Honored.—Dr. Max Cutler, director of the Chicago Tumor Institute, will be honored at an all day meeting on the cure and control of cancer in Atlanta, Ga., March 29. The sessions will start at 10 a. m. in the Henry Grady Hotel and will be under the sponsorship of the state department of health, the Cancer Commission of the state Association of Georgia and the Georgia Division of the Women's Field Army of the American Society for the Control of Cancer. Principal speakers at the morning session will be Dr. Cutler and Dr. Leonard A. Scheele, U. S. Public Health Service, Washington, D. C., who will discuss "Early Diagnosis and Treatment of Cancer" and "Cancer as a Public Health Problem" respectively. In the afternoon a conference on the diagnosis and treatment of cancer with the exhibition of cases will be held at the Sheffield Cancer Clinic of the Georgia Baptist Hospital. In the evening Dr. Cutler will be presented with an official citation by Governor Rivers in recognition of his "outstanding achievement in the realm of cancer cure and control." At the same time he will be appointed an honorary lieutenant colonel on the military staff of the governor. Dr. Cutler formerly lived in Athens and graduated at the University of Georgia in 1918.

MASSACHUSETTS

Society News.—At a meeting of the New England Society of Physical Medicine, February 28, a symposium on the treatment of arthritis was presented by Drs. James Sydney Stillman Jr., Jose P. Bill, Herman A. Osgood and Loring T. Swaim, Boston.—Dr. William A. Malamud discussed "The Problem of the Neuroses in General Practice" before the Worcester District Medical Society, February 14, and Saul Rosenzweig, Ph.D., "Experimental Neurosis."—Civic and other agencies are cooperating in the second Worcester Health Week, February 25-March 2, initiated by the Worcester

New Department of Anatomy at Tufts.—Dr. and Mrs. George G. Averill, Waterville, Maine, have given \$42,200 to the Tufts College Medical School, Boston, to establish the "Dr. and Mrs. George G. Averill Department of Anatomy in Memory of Prof. Charles P. Thayer." Dr. Thayer was one of the "original seven" founders of the school in 1893 and first head of the anatomy department. Dr. Averill graduated from Tufts in 1896. The gift will provide the entire top floor of a new medical school building which will be situated in downtown Boston at the New England Medical Center. The gift will be made available during 1940 and 1941, the announcement stated.

MISSISSIPPI

Hospital News.—The new Beacham Memorial Hospital was dedicated at Magnolia recently with Dr. Rudolph Matas, New Orleans, giving the principal address.

Society News.—Members of the faculty of the University of Mississippi School of Medicine, University, recently presented the following program before the Clarkdale and Six Counties Medical Society at Clarkdale: Dr. Robert M. Moore, "Mortality in Appendicitis"; David S. Pankratz, "Influence of Barbiturates on the Gravid Uterus"; James B. Loooper, "Treatment of Narcolepsy"; Vernon B. Harrison,

"Diagnosis of Gonorrhea"; Eugene V. Bramlett, "Leukorrhea"; James R. Simms Jr., "Conservative Treatment of Pelvic Inflammatory Disease"; Wilbur F. Potter, Ph.D., "Cardiac Physiology," and Robert P. Walton, Ph.D., "Pharmacology of Cardiac Drugs."

Personal.—Drs. W. H. Banks, Philadelphia, and Samuel E. Eason, New Albany, were recently appointed members of the state board of health for five year terms.—Dr. Byron O. Garner, Greenwood, of the Adams County Health Department, has been appointed temporary health officer in LeFlore County, filling the vacancy caused by the death of Dr. Levi A. Barnett, Greenwood.—Dr. Isaac C. Farmer, formerly of Mendonhall, has been selected to be health officer of the newly formed health unit in Tate County with headquarters in Senatobia.—Dr. Francis S. Dixon has been appointed superintendent of the Natchez Charity Hospital in Natchez, succeeding Dr. Louis M. Magee, resigned.

NEW JERSEY

Society News.—Dr. William Wayne Babcock, Philadelphia, addressed the Essex County Medical Society, Newark, March 14, on "Surgical Considerations in Intestinal Obstruction."—Dr. Horace J. Williams, Philadelphia, addressed the Camden County Medical Society, Camden, March 5, on "Otitis Media and Mastoiditis."—Dr. Leon Herman, Philadelphia, will address the Academy of Medicine of Northern New Jersey, Newark, March 21, on "Urogenital Tuberculosis." Dr. Alfred W. Adson, Rochester, Minn., presented a paper before the section on medicine and pediatrics, March 12, on "Diagnosis and Treatment of Recurring Sciatica."

NEW YORK

State Society Moves.—Offices of the Medical Society of the State of New York, which have been in the building of the New York Academy of Medicine since 1926, have been moved to an entire floor in the Research Institute Building, 292 Madison Avenue, New York.

Physician Leaves Fund for New Building.—Dr. Dewitt H. Sherman, for many years professor of pediatrics at the University of Buffalo School of Medicine, left a bequest of about \$225,000 to the university for a new medical building, according to the *New York State Journal of Medicine*. In addition, Mrs. Sherman has made a gift of \$200,000 for the fund. Dr. Sherman died February 1.

Buffalo Clinical Day.—The University of Buffalo School of Medicine will sponsor the Sixth Annual Clinical Day, April 20, with the following guest speakers:

- Dr. Newton D. Smith, Rochester, Minn., The General Practitioner's Anorectal Problems.
- Dr. James G. Carr, Chicago, Obscure Fever.
- Dr. Albert M. Snell, Rochester, Minn., Some Problems Presented by the Jaundiced Patient.
- Dr. Henry M. Thomas Jr., Baltimore, Hypertension: The Modern Conception of Its Causes and the Results of Medical and Surgical Treatment.
- Dr. Temple S. Fay, Philadelphia, Observations on Human Refrigeration.

New York City

Sixth Harvey Lecture.—René J. Dubos, Ph.D., associate member, Rockefeller Institute for Medical Research, will deliver the sixth Harvey Society Lecture of the current series at the New York Academy of Medicine, March 21. His subject will be "Utilization of Selective Microbial Agents in the Study of Biological Problems."

In Memory of Dr. Farrand.—A memorial meeting in honor of the late Dr. Livingston Farrand was held at the New York Academy of Medicine on January 30 under the auspices of various organizations with which Dr. Farrand was associated. The speakers were:

- Charles F. W. McClure, Sc.D., Princeton, N. J., representing the class of 1888 at Princeton University, of which Dr. Farrand was a member.
- Dr. Charles J. Hatfield, Philadelphia, the National Tuberculosis Association.
- Homer Folks, LL.D., the Rockefeller Tuberculosis Commission in France.
- Eliot Wadsworth, LL.D., Boston, the American Red Cross.
- Albert R. Mann, LL.D., Cornell University.
- Dr. James Ewing, Cornell University Medical College.
- Albert G. Milbank of the Milbank Memorial Fund, whose address was read by Dr. Frank G. Boudreau.
- Dr. Thomas Parran, Washington, D. C., the U. S. Public Health Service.
- Dr. Simon Flexner, the Public Health Council of the State of New York.
- Barklie Henry, the New York Hospital.
- George E. Vincent, Ph.D., the Rockefeller Foundation.

OHIO

University News.—Dr. Leonard G. Rowntree, Philadelphia, will deliver the Roger Morris Memorial Lecture for 1940 at the University of Cincinnati College of Medicine, March 25. Dr. Rowntree's subject will be "The Suprarenal Gland and Its Diseases."

Personal.—Dr. Claude V. Davis, Pennsville, has been appointed a member of the state medical board to succeed the late Dr. Lee Humphrey, Malta.—Dr. Benjamin W. Dudley Keever, Centerville, was honored by the Montgomery County Medical Society at a meeting in Dayton, January 15, on his completion of fifty-five years of practice. The society gave him a fountain pen and pencil set.—Dr. Howard Dittick, Cleveland, has been appointed editor of *Current Researches in Anesthesia and Analgesia*, succeeding the late Dr. Francis Hoeffler McMechan, Rocky River.

OREGON

New Health Officers.—Dr. Frederick T. Burke, Timber, has been appointed health officer of Washington County, succeeding Dr. Richard N. Sherwin, Hillsboro, who resigned.—Dr. Charles J. Hedlund, formerly of Atwater, Minn., has been appointed health officer of a new health unit in Baker County.

Personal.—Dr. John E. Weeks, Portland, has been appointed honorary professor of ophthalmology at the University of Oregon Medical School, Portland. Dr. Weeks, now 86 years old, was for many years professor of ophthalmology at University and Bellevue Hospital Medical College, New York, and has been professor emeritus since 1920. He was chairman of the Section on Ophthalmology of the American Medical Association in 1902 and president of the American Ophthalmological Society in 1923.

PENNSYLVANIA

Hospital News.—A new \$600,000 children's preventorium was placed in operation recently at the Pennsylvania State Tuberculosis Sanatorium at South Mountain in Franklin County. The building will accommodate 340 children; 215 were moved into it from the old buildings.

Medical Service Plan Approved.—The house of delegates of the Medical Society of the State of Pennsylvania at a special meeting in Harrisburg, February 28, voted to establish a low cost medical service plan for wage earners in the lower income brackets. The plan would be put in operation first in the fifth councilor district, including Dauphin, Cumberland, Lebanon, York, Adams, Lancaster, Franklin, Fulton and Perry counties. Rates, as reported in a newspaper account, will be \$2.50 a month for a single member, \$2 additional for his wife, \$1.50 additional for one child and \$1 for each additional child.

Society News.—Dr. Julius M. Rogoff, Pittsburgh, addressed the annual combined dinner meeting of the Valley Medical Society and the McKeesport Academy of Medicine, February 26, on "Endocrinology: Its Present Status."—Dr. William A. Marsh, Mount Pleasant, among others, addressed the Westmoreland County Medical Society, March 5, at the Mountain View Hotel near Greensburg on "Treatment of Hip Joint Fracture in the Aged."—Dr. Tom Outland, Elizabethtown, addressed the Dauphin County Medical Society, Harrisburg, March 5, on "Treatment of Compressed Fracture of the Spine."—Dr. Joseph C. Yaskin, Philadelphia, addressed the Harrisburg Academy of Medicine, February 20, on "Painful Conditions Related to the Peripheral Nerves and Their Roots."

Philadelphia

Meeting on Cancer.—The Philadelphia County Medical Society devoted its meeting, March 13, to a program on cancer. The speakers were William U. Gardner, Ph.D., New Haven, Conn., on "Relation of Hormones to Cancer"; Drs. Edmund P. Halley, Decatur, Ill., "Preoperative Irradiation in Breast Carcinoma with Microscopic Studies"; Catharine Marfarlane, "An Experiment in Cancer Control," and Stanley P. Reimann, progress report from the division of cancer control, Pennsylvania Department of Health.

Society News.—Dr. Oscar V. Batson addressed the Philadelphia Laryngological Society, March 5, on "The Circulation of the Head, Especially Venous, with Reference to Osteomyelitis, Brain Abscess and Malignant Metastasis."—Dr. Alvin F. Coburn, New York, addressed the College of Physicians of Philadelphia, March 6, on "Faulty Handling of Streptococcus Haemolyticus in Relation to the Development of the Rheumatic Lesion."—Speakers at a meeting of the Obstetrical Society of Philadelphia, March 7, were Drs. Newlin F. Paxson on "Chronic Nephritis and Pregnancy," and Franklin L. Payne

and Craig W. Muckle, "Clinical Experience with Stilbestrol."—Dr. Readie Garfield Snyder, New York, addressed the Philadelphia Rheumatism Society, March 7, on "Therapy of Chronic Arthritis; Including a Discussion of the Use of Gold Salts and a Preliminary Report on the Use of Activated Ergosterol."

TEXAS

Dallas Hospital Institute.—The Dallas County Hospital Council is sponsoring a hospital institute in Dallas during the week of April 8 for employees of the member hospitals. Meetings will be held every evening at St. Paul Hospital, with papers covering many phases of hospital activity, followed by panel and round table discussion. Speakers are drawn from local hospitals. Twenty-four institutions are affiliated with the hospital council. Hospital employees in adjacent communities have been invited to attend. Mr. A. C. Seawell, assistant superintendent of the Baylor Hospital, is president of the council.

Society News.—Drs. Thomas E. Smith and James H. Herndon addressed the Dallas County Medical Society, Dallas, February 8, on "Surgical Treatment of Hemorrhoids," and "Typhus Fever" respectively. Speakers before the society, March 28, will be Drs. Charles D. Bussey, on "Gastrojejunal Ulcer—A Sequel to Gastric Surgery"; Milford O. Rouse and Cecil O. Patterson, "Foreign Bodies in the Stomach as Observed Through the Flexible Gastroscope," and Walter G. Reddick, "Treatment of Pneumonia with Sulfanilamide, Sulfapyridine and Sulfathiazol."—Drs. William W. Fowler and Max H. Grow, Dallas, addressed the Denton County Medical Society, February 1, on "Diagnosis and Treatment of the Ophthalmological and Rhinological Manifestations of Allergy" and "Allergy in Childhood" respectively.

WASHINGTON

Puget Sound Surgical Society.—Dr. Howard K. Gray, Rochester, Minn., was the guest speaker at the annual meeting of the Puget Sound Surgical Society in Seattle, March 8-9. Dr. Gray made an address on "Problems Associated with Occlusive Diseases of the Extrahepatic Bile Ducts." He conducted clinics Saturday at the King County Hospital and at the formal banquet in the evening spoke on "Significance and Surgical Management of Ulcerating and Neoplastic Lesions of the Stomach."

Society News.—Dr. Owen H. Wangensteen, Minneapolis, will be the guest speaker at the annual meeting of the Tacoma Surgical Club, March 23. The general subject for the day will be "Complications of Abdominal Surgery."—A symposium on mental diseases was presented at a meeting of the Spokane County Medical Society, Spokane, February 8, by Drs. Marinus W. Conway, Harry N. Roback, Cecilia E. Schlotthauer, Herbert A. Perry and Charles W. Miller Jr., all of the staff of the Eastern State Hospital, Medical Lake. Dr. Herbert E. Coc, Seattle, addressed the Walla Walla Valley Medical Society, Walla Walla, February 14, on developmental and congenital defects. Dr. Carl P. Wagoner, Seattle, addressed the Pierce County Medical Society, Tacoma, February 13, on "The Common Cold."

WISCONSIN

District Meeting.—The Ninth Councilor District Medical Society held its winter meeting in Wisconsin Rapids on January 25 with the following speakers: Drs. Lyman A. Capps, Marshfield, on "External Eye Diseases"; Allen L. Millard, Marshfield, "Pericarditis," and Ovid O. Meyer, Madison, "Recent Advances in Hematology."

University News.—Dr. Walter Freeman, Washington, D. C., addressed the University of Wisconsin Medical Society, Madison, February 14, on "Experiences in the Treatment of Schizophrenia by Means of Prefrontal Lobotomy." Dr. James W. Kernohan, Rochester, Minn., gave a lecture under the auspices of Alpha Omega Alpha at the university, March 8, on "Cerebral Changes Associated with Endocarditis."

Society News.—Drs. Manfred W. Comfort and Howard K. Gray, Rochester, Minn., discussed medical and surgical aspects, respectively, of diseases of the gallbladder and surgical treatment of the gallbladder at a meeting of the Polk County Medical Society, Balsam Lake, January 18. Dr. Henry A. Sincok and James W. McGill, Superior, addressed the Chippewa County Medical Society, Chippewa Falls, January 23, on "The Practical Problem of the Physician Doing a Combined Obstetric and Pediatric Practice" and "Con-

traction Ring Dystocia" respectively. Dr. Joseph M. King, Milwaukee, addressed the Fond du Lac County Medical Society, Fond du Lac, January 18, on "Hand Infections."—Dr. Frederick A. Collier, Ann Arbor, Mich., was the guest speaker at the meeting of the Medical Society of Milwaukee County, February 9, on "The Diagnosis of Acute Abdominal Surgical Lesions."—Dr. Albert D. Kaiser, Rochester, N. Y., addressed the Milwaukee Pediatric Society, February 14, on "The Tonsil Question" and Dr. Francis D. Murphy, Milwaukee, on "The Fluid Balance."

GENERAL

Meetings in Pittsburgh in March.—The American Association of Pathologists and Bacteriologists will have its fortieth annual meeting in Pittsburgh at the Mellon Institute, March 21-22. Among more than fifty papers will be the following:

Dr. Frank L. Apperly, Richmond, Va., The Significance of the Varying Distribution of Cancer in North America.
Drs. John T. Bauer and Paul H. Schraer, Philadelphia, Late Pathologic Effect of High Voltage X-Rays on the Human Lung.
Dr. Stuart W. Lippincott, Montreal, Canada, Histopathologic Studies on a Fatal Case of Hypervitaminosis D.
Dr. Simeon Buri Wolbach, Otto A. Bessey, Ph.D., and Dr. Roy L. Swank, Boston, Vitamin Deficiency and Lesions of the Nervous System.
Drs. Robert C. Grauer, Chester F. Beall and George R. Wilson, Pittsburgh, Endometrial Response to Stilbestrol in Radium Menopause.
Drs. George R. Lacy and Mortimer Cohen, Pittsburgh, The Bacteriology of Postpartum Febrile Conditions.
William H. Feldman, D.V.M., and Dr. Henry F. Helmholz, Rochester, Minn., The Presence of Viable Tubercle Bacilli in Lesions of the Glial Complex of Children.
Dr. Warren C. Hunter, Portland, Ore., Etiology, Incidence and Fate of Deep Leg Vein Thrombosis in 300 Unselected Autopsies.

The American Association for Cancer Research will meet at the Mellon Institute, March 19-20, with the following speakers, among others:

Dr. Emmerich V. Haam and Leona Cappel, Columbus, Ohio, The Influence of Hormones Upon Cells Grown in Tissue Culture.
Dr. Joseph H. Farrow, New York, Treatment of Inoperable Carcinoma of the Breast with Testosterone Propionate.
Murray J. Shear, Ph.D., and Dr. Harold L. Stewart, Bethesda, Md., Carcinogenic Activity of Nitrogen-Containing Benzene Derivatives.
Drs. Michael B. Shimkin and Hugh G. Grady, Bethesda, Md., Carcinogenicity of Stilbestrol and Estrone.
Fritz Bischoff, Ph.D., M. Louisa Long and Dr. John Jerome Rupp, Santa Barbara, Calif., Influence of Induced Hibernation on the Growth Behavior of Mouse Neoplasms.

The American and Canadian Section of the International Association of Medical Museums will hold its thirty-third annual meeting March 20, with an exhibition at Mellon Institute for the benefit of all the societies, March 20-22. A special feature of the program will be a symposium on the use of plastics in museum work. Col. James E. Ash, curator of the Army Medical Museum, Washington, D. C., is president of the section.

American College of Physicians.—The twenty-fourth annual session of the American College of Physicians will be held in Cleveland, April 1-5, with headquarters at the Cleveland Public Auditorium and under the presidency of Dr. Oliver H. Perry Pepper, Philadelphia. The annual convocation will be Wednesday evening, April 3, when Dr. Pepper will give his official address; Dr. Charles F. Martin, emeritus dean and emeritus professor of medicine, McGill University Faculty of Medicine, Montreal, Canada, will give the convocation address, and the John Phillips Memorial Medal will be presented to René J. Dubos, Ph.D., New York. One general session will be devoted to a symposium on military medicine with speakers from the U. S. Army and Navy. Among the speakers at other sessions will be:

Drs. Joseph Kaufmann and Louis Lowenstein, Montreal, A Study of the Acute Leukoses.
Drs. Harrison F. Flippin and Leon Schwartz, Philadelphia, The Comparative Effectiveness of Sulfathiazol and Sulfapyridine in Pneumococcal Pneumonia.
Dr. Everett N. Collins, Cleveland, Treatment of Ulcerative Colitis with Sulfanilamide.
Dr. George W. Thorn, Baltimore, The Role of the Gonadal and Adrenal Cortical Hormones in the Production of Edema.
René J. Dubos, Ph.D., New York, The Effect of Specific Agents Extracted from Soil Micro-Organisms Upon Experimental Bacterial Infections.
Drs. Henry Field Jr., William D. Robinson and Daniel Melnick, Ph.D., Ann Arbor, Mich., Vitamins and Pernicious Anemia.
Dr. Edward L. Bortz, Philadelphia, Special Ulcer.
Dr. Mark P. Schulz, U. S. Public Health Service, Washington, D. C., Blood Cholesterol in Rheumatic Fever.
Dr. George Gill Richards, Salt Lake City, Tularemia Pneumonia.
Dr. Louis E. Priekman and Herman J. Moersch, Rochester, Minn., Broncho-pneumonia Complicating Allergic and Infectious Asthma.

General sessions will be held in the afternoons with the exception of the symposium on military medicine, which will be Monday evening. Mornings will be devoted to clinics and demonstrations in Cleveland hospitals and to lectures at the auditorium. A program of panel discussions will be presented

each afternoon just before the general sessions. The annual banquet will be Thursday evening, with Dr. Howard T. Karsner, Cleveland, as toastmaster and Mr. Grove Patterson, editor of the *Toledo Blade*, as the speaker.

Bequests and Donations.—The following bequests and donations have recently been announced:

Children's Memorial Hospital, Chicago, \$25,000 by the will of Mrs. Della Ross Stack.

International Cancer Research Foundation, Philadelphia, \$100,000 (with the exception of a few minor bequests) from the will of the late Mrs. Gertrude Wellington as a memorial to her husband, who died of cancer.

University of Pennsylvania Hospital, Philadelphia, \$15,000 to endow a free room and a free bed.

Jewish Hospital, Philadelphia, \$2,000 by the will of the late Bernard Selig.

St. Christopher's Hospital for Children, Philadelphia, \$3,000 by the will of the late Elijah Dallett.

Lankenau Hospital, Philadelphia, \$5,000 from the estate of William H. Norris after the remarriage or death of his widow, and \$10,000 for maintenance of two beds by the will of the late Julia Preuss.

Quakertown Hospital, Quakertown, Pa., \$10,000 from the estate of Miss Emma Roeder and \$2,500 from the estate of a Miss Sterner.

Presbyterian and Lankenau hospitals, Philadelphia, will share approximately \$8,500 from the estate of Miss Minerva Booth, following a settlement in the Orphans' Court.

Government Services

Army Experience for Physicians

Physicians under 35 years of age who are desirous of obtaining extended active duty with the army but who do not hold reserve commissions are being offered appointments in the Medical Corps Reserve in the grade of first lieutenant, in order to permit them to be placed on such duty. Captains and lieutenants are at present being offered excellent assignments throughout continental United States, and it is hoped that authority will be granted to permit some officers to go to Hawaii and Panama. In addition to having a new and busy experience in the practice of medicine, the average officer finds the pay and allowances attractive. The pay and allowances for a married first lieutenant amount to approximately \$263 a month; for a single first lieutenant to approximately \$225 a month; for a married captain to approximately \$316 a month, and for a single captain to approximately \$278 a month. In most cases the pay and allowances would apply, as government quarters are not usually available for officers on extended active duty. In the few instances in which government quarters are available, the amounts would be \$40, \$60, \$60 and \$80 less per month respectively. In addition, the officer is reimbursed for mileage traveled from his home to his station, and on completion of his tour of duty he is reimbursed similarly for the travel to his home.

Application for one year of active duty, or for appointment in the Medical Corps Reserve with a view to obtaining one year of active duty with the army, should be requested at once by a letter addressed to the commanding general of the corps area wherein the physician permanently resides. In addition, the application should contain concise information regarding permanent address, temporary address, number of dependents, earliest date available for active duty, and the fact that internship has been (or will be) completed; it should be accompanied by a report of physical examination recorded on the army form W. D. A. G. O. 63, which may be obtained from any army station. From the group of reserve officers placed on extended active duty since August 1939, more than 25 per cent of those within the age requirements of 32 years of age or less for commission in the regular army Medical Corps found military service sufficiently to their liking to cause them to take entrance examinations for the regular army. Corps areas and their headquarters are as follows:

First Corps Area (Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut), Army Base, Boston, 9.

Second Corps Area (New York, New Jersey, Delaware), Governor's Island, New York.

Third Corps Area (Pennsylvania, Maryland, Virginia, District of Columbia), Post Office and Court House, Baltimore.

Fourth Corps Area (North Carolina, South Carolina, Georgia, Florida, Alabama, Tennessee, Mississippi, Louisiana), Post Office Building, Atlanta, Ga.

Fifth Corps Area (Ohio, West Virginia, Indiana, Kentucky), Fort Hayes, Columbus, Ohio.

Sixth Corps Area (Illinois, Michigan, Wisconsin), Post Office Building, Chicago.

Seventh Corps Area (Missouri, Kansas, Arkansas, Iowa, Nebraska, Minnesota, North Dakota, South Dakota), New Federal Building, Omaha.

Eighth Corps Area (Texas, Oklahoma, Colorado, New Mexico, Arizona), Fort Sam Houston, San Antonio, Texas.

Ninth Corps Area (Washington, Oregon, Idaho, Montana, Wyoming, Utah, Nevada, California), Presidio of San Francisco, San Francisco.

The Medical Profession and the War

A Central Medical War Committee, representing all branches of the medical profession, has been set up under government plans. To this committee the government refers all questions regarding the supply of medical personnel arising out of the war. It satisfies the demands for this personnel both for the civil population and for central and local government authorities. In every area of the country there is a local medical war committee through which the central committee operates. The local committees will be reelected next March and thereafter annually. Before allocating a practitioner for national service, the central committee consults the local committee of the area in which the practitioner resides. The demand is distributed in the form of quotas among the local committees, regard being paid to such local factors as density of population and proportion of practitioners in the area. The local committee satisfies the quota in such a way as will secure the least interference with local medical services and the greatest possible regard to the wishes of the individual practitioner. Similarly, demands for specialist personnel are received from the services in numerical form for surgeons, anesthetists, dermatologists, venereologists, psychologists, radiologists and so on. The central committee satisfies itself as to the specialist qualifications and experience of the individuals before recommending them for appointment. But in the case of London practitioners a committee of the royal colleges, known as the Committee of Reference, has the responsibility of approval.

At present no practitioner can be allocated to the services without his consent. This arrangement will continue as long as the whole medical profession is included in "the reserved occupations." But conscription may be applied to the medical profession. If and when this occurs, it is anticipated that the same central and local arrangements will continue and regard be paid to the wishes of practitioners, though the needs of the country must be paramount. Heavy demands for medical personnel for general duty with the forces are now being received. The scheme of the British Medical Association for the protection of practitioners for whole time war service is in general operation.

The Medical Uses of Radium

The Medical Research Council has published a summary of the research work done with radium or radon during 1938 at more than twenty hospitals and other institutions, most of which hold radium on loan from the council. The discovery of neutron in 1932 and of artificial radioactivity in 1934 aroused great interest. But the prediction that artificial radioactive bodies would replace radium is not yet in sight of fulfillment. One of the council's staff, Dr. F. G. Spear, joined in a biologic research on neutron action from October 1938 to March 1939 with Prof. John H. Lawrence in California, where the first cyclotron was installed. As a result of his report facilities are to be provided in this country for research on neutron irradiation by means of a cyclotron.

CANCER OF THE BREAST

At the Marie Curie Hospital, London, removal is advocated in operable cases. Cases considered to be on the borderline of operability are given preoperative roentgen treatment followed by removal. Either a lethal dose is given, followed by operation several months afterward, or a modified x-ray dose is followed by operation in from seven to ten days. Whether subsequent postoperative treatment is given depends on the clinical and pathologic appearance. The mode of access is by two fields,

one medial and the other lateral, to include the breast and the axilla. Inoperable cases are generally treated by x-rays. A few have been given interstitial radium or a combination of the two. Recurrences are treated mainly by x-rays or telerradium.

At St. Bartholomew's Hospital a histologic investigation of the effects of radium, begun in 1932, has been completed. Of fifty specimens of breast and axillary contents removed three months after radium had been inserted, active-looking carcinoma cells were present in ten, degenerate cells in seventeen and no residual growth in the remaining twenty-three. There is some evidence that gland deposits vary, like the primary growth, in their response to radium. Although there were several striking cases in which large axillary metastases disappeared, fourteen of fifty specimens showed active growth in the glands three months after what had been regarded as adequate irradiation.

CANCER OF THE LARYNX

The Birmingham General Hospital reports that since 1934 all cases of intrinsic cancer of the larynx considered suitable have been treated by the fenestration method associated with the names of Finzi and Harman and that this has given good results in several cases of precancerous conditions of the larynx. This operation is considered to have a wider field than laryngofissure. It has been extensively applied to neoplasms which have not only invaded one cord but have extended round the commissure to the other. The technic consists in exposure of the thyroid ala and cutting a window subperichondrially in the cartilage so as to accommodate from eight to ten needles, each containing 1 mg. of radium, placed side by side across it. At the original operation difficulty was found in getting the skin incision to heal. This has been overcome by smearing the site of implantation with a paste of bismuth subnitrate and iodoform.

TELERRADIUM THERAPY

The most extensive investigation of telerradium therapy has been at the Radium Institute, London. The volume of tissue irradiated has comprised the primary growth and its probable direction of spread. The direction of the beam is so determined that a homogeneous radiation is delivered to the whole of this tissue block. To minimize the total amount of radiation delivered to the patient's body, the primary growth is irradiated through the glandular regions. A dose of from 5,000 to 8,000 roentgens has been delivered in forty-two days. When the growth is early and localized, complete disappearance can be expected. Affected lymphatic glands in close proximity also disappear. When the primary growth and the glands are in an advanced and inoperable stage, the disease can be made to disappear in a small proportion of cases and distressing symptoms may be relieved in a large proportion. It is too early to make definite pronouncements, but it appears that the treatment of carcinoma of the mouth and throat by the radium beam is at least as satisfactory as by surgery or interstitial radium. In cancer of the breast the beam is directed to the primary growth by glancing fields across the surface of the body so as to avoid overirradiation of the structures beneath the breast.

Speed Acceleration During Flight

Dr. Gauer recently discussed in *Der deutsche Militärarzt* the effect of speed acceleration on air pilots. He said that the least indisposition of the pilot, lasting less than a second, is sufficient to produce a catastrophe, in view of the fact that even under optimal conditions of a normal reaction time of 0.2 second the airship at a speed of 600 kilometers an hour covers a distance of 30 meters unsteered before the pilot, guided by optical sense impressions, is able to maneuver. The cause of the disturbances which may arise does not lie in the speed itself but in the centrifugal force involved. Experiments made during recent

years showed that endurance depends chiefly on the magnitude of centrifugal force, on its direction and duration, on individual variations and on the position of the pilot. At the heart of the problem are the changes in hydrostatic pressure in the vascular system. Strenuous flights should not be taken without a breakfast. To take off on an empty stomach or on only a cup of tea or a cigaret, as is usually done, means a decided loss of power of resistance in the endurance of speed acceleration. It is safer to avoid as much as possible the action of centrifugal force than to resist it by increasing vascular regulation. The best course is to place the pilot in his ship on his back or his stomach. The circulation can then endure great speed acceleration without strain. However, the technical difficulties of placing the pilot in a dorsal or ventral position are immense. An increased power of resistance cannot be acquired by training. During the progress of infectious diseases, and immediately after, the power to resist the action of centrifugal force is low, no matter whether the infection is relatively harmless or not. The limits of human endurance of speed acceleration in air navigation have not yet been reached.

Insulin Shock Therapy

Dr. Büdingen reported to the Berlin society of psychiatrists and neurologists the results obtained with insulin shock therapy in the free psychiatric clinic of the University of Berlin. Insulin was given to 134 patients, fourteen of whom were nonschizophrenic. Complete remissions amounted to 11.2 per cent, social remissions to 16.4 per cent, amelioration to 17.1 per cent and no influence to 55.3 per cent. If nonschizophrenic cases are excluded, 61.7 per cent remained uninfluenced. The treatments were carried out strictly according to Sakel's procedure and lasted on the average three months. Improvements were often only transient. Büdingen regards insulin therapy as contra-indicated in true schizophrenia but indicated in cases of psychosis that show symptoms occurring in schizophrenia but which, according to their complete clinical picture, require different classification.

Gonorrheal Arthritis Secondary to Blood Transfusion

At the Children's Hospital in Cluj, A. Janeu, C. Oprisiu and N. Domincovici in the *Monatsschrift für Kinderheilkunde* reported the case of a male infant aged 8 months, suffering from furunculosis. Two transfusions of the mother's blood were undertaken. Four days later the infant's temperature rose and painful swellings of several joints set in. An exploratory puncture disclosed gonococci. The infant was treated with azosulfamide and the condition healed except for a few traces. The infant's mother had been suffering from arthritis for nine years, a sequel to gonorrhea. No gonococci were found in her blood. In spite of this negative finding the child's arthritis must be attributed to the blood transfusions, because determination of gonococci in the blood is rarely successful.

Personal

Prof. Ludwig Fraenkel, former professor of gynecology and obstetrics in Breslau, completed his seventieth birthday April 23. A pupil of the pathologic anatomist Grawitz and of gynecologists Hegar, Sänger and W. A. Freund, he began his academic career in Breslau in 1905 and became associate professor in 1909 and full professor and director of the university woman's clinic in 1922. In 1934 he, like many others, was retired. Fraenkel's scientific contributions in his field deal with the function of the corpus luteum, hydatid moles, choriomas, placenta praevia, ovulation and menstruation. His monographs on the normal and pathologic sex physiology in woman, the physiology of female genital organs and clinical pathology of tumors of endocrine glands in relation to the genital system and his books on social obstetrics and gynecology (1928) and the prevention of conception (1932) were much discussed. Fraenkel, whose

personality and ability as a clinician and teacher are greatly esteemed and who lectured in the United States on several occasions, is now living in Montevideo, Uruguay, and is active as a gynecologic consultant. A dedicatory issue of the *Anales de la Facultad de Medicina de Montevideo* is in preparation, in which also North American physicians are largely represented.

STOCKHOLM

Jan. 7, 1940.

The Transport of the Sick and Injured

The problem of motor ambulance services throughout Sweden has of late been tackled from several angles, and many of the advances made must be put to the credit of Surgeon General (retired) Fritz Bauer, whose activity in this field has been ceaseless. The Hospital Standardization Committee and the National Red Cross Society first explored the possibilities of providing the country, rural areas included, with an efficient network of motor ambulances. But, as the years passed and the toll of the roads mounted every year, it became obvious that the motor ambulance was by itself a too costly solution of the problem. Attention was therefore turned to other possibilities, such as the conversion of motor busses, motor lorries and motor cars, both private and for hire, into extemporized motor ambulances. It is particularly the ordinary motor car which at the present time is receiving attention as the most likely key to the riddle.

There are already some 300 motor cars in Sweden fitted so as to be converted into extemporized motor ambulances in an emergency, and among the taxicabs in Stockholm there are twenty-five which can serve this purpose. Their owners are under contract with the Stockholm hospital service to turn them into motor ambulances when required. Surgeon General Bauer advises the prospective purchasers of private motor cars to stipulate with the makers for the necessary fittings without any extra charge. When a car has already been purchased, and when it conforms to the standardized requirements of extemporized motor ambulances, it is possible to make the necessary changes at a cost of less than 100 kronor (\$24). The standardized stretcher need not cost more than from 60 to 70 kronor (about \$15). A four seater can be fitted to take one recumbent patient on the stretcher in addition to one person sitting up and the driver. A seven seater can be made to accommodate one stretcher patient and three persons sitting up, as well as the driver. Alternative disposals of the stretcher have been devised, but the most effective system is the one in which the stretcher is introduced into the car from behind and is secured to the floor of the car. Under the guidance of Dr. Rolf Bergman, who is in charge of the fever hospital of Stockholm, instructions have been drafted for the disinfection of extemporized motor ambulances after they have conveyed infectious cases. These instructions are printed on the back of the contract between the car owner and the hospital authorities.

The Frequency of Mild Chronic Encephalitis

In the old university town of Lund, Prof. Henrik Sjöbring has for several years made his psychiatric clinic a remarkably effective clearing house for all sorts and conditions of ailments for which only a generation ago there would have been no appropriate labels. To be sure, the process of labeling is at times still somewhat tentative, and the dividing line between functional psychoses and psychoses with an organic basis is not always as clearcut as one would like. Every patient attending this clinic undergoes an analysis of his personality with a view to its basic features, before the development of serious symptoms, being made clear. Such an analysis is often helpful in linking up troublesome symptoms of the present with constitutional characteristics in the past. As the weeding out proceeds, it becomes possible to give such labels as slight schizophrenia,

syphilis of the central nervous system, and psychoses with a traumatic, epileptic or toxic basis.

In addition to these psychoses, which can be accounted for by a reference to some organic lesion or other, there is a quite large group which till recently has baffled definition and which would now seem quite appropriately to come under the diagnosis of mild chronic encephalitis. Dr. Erik Rydén, who is attached to Professor Sjöbring's clinic, has undertaken a special study of this condition, which he has found so common that some fifty cases of it can be recognized as such every year at this clinic. Though the basis is organic, the psychic symptoms are so dominating that it is little wonder that these patients often are sent to a psychiatric hospital. The patient often refers the onset of his troubles to some infectious disease such as influenza or measles, since which he has never been quite well. Diseases due to some virus or other would seem to be particularly important as etiologic factors. How far epidemic encephalitis is to blame is not yet clear. As for the symptoms, they are remarkably similar to those of the menopause, although every age and both sexes are represented. While prolonged rest in bed is probably the best treatment, at any rate early in the disease, the mistake is often made in prescribing more heroic measures, such as artificial fever, on the assumption that schizophrenia is to blame. Indeed, much of the importance attaching to the identification of these cases concerns their treatment; the patient needs rest and quiet surroundings, not the radical procedures now in vogue for schizophrenia or the studied neglect apt to be meted out to the subjects of more or less purely functional disturbances of the central nervous system.

What Is General Medical Practice?

There has been much discussion concerning the medical curriculum and the need for modifying it to meet the requirements of medical practice. From which end of the line are reforms to come? From the teachers? From the general practitioners who have grown old at their work and who, in retrospective mood, can tell both the teachers and their pupils what is needed most? With regard to this last question Dr. Hjalmar Sjövall, of Lund, has some pertinent facts to relate. He has undertaken a comprehensive study of the clinical notes and records of a colleague, a general practitioner in a town large enough to possess a hospital of its own. The records concern 1,000 consecutive cases seen in the course of some eight months of general practice. It should be noted that this figure refers to cases, not patients. In other words, one and the same patient with a fracture on one occasion and pneumonia on another would appear on the records as two cases. It was hoped that by means of an analysis of these records, of what was done for each case, to gain an insight into the duties and activities of a Swedish general practitioner at the present time.

What a mixture such a survey presents! In about 13 per cent of all his cases, the doctor found it necessary to send his patients to a hospital or to some specialist. A classification of the ailments brought to light the fact that as many as 200 were cases of cold in the head, sore throat, cough, hoarseness, or pain in the back or in the whole body, with or without fever. This figure could be brought up to 231 under the heading diseases of the respiratory system. As many as fifty cases were labeled neuroses and ten psychoses. Altogether there were 160 cases which could be classified as nervous disturbances. Again, there were as many as 132 cases of disease of the digestive tract. Dr. Sjövall's conclusion from this study is that one of the most important functions of the general practitioner is to sort out from a huge mass of trivial cases the very few requiring early diagnosis with the skilled treatment which alone can be expected to restore the patient to health. With highly skilled treatment in the hands of specialists, what is wanted of the general practitioner is above all diagnostic skill.

FINLAND

(From a Special Correspondent)

Feb. 15, 1940.

Medical Aspects of the War in Finland

In spite of the censorship it is now possible to glean and pass on a good deal of information concerning happenings of special interest to the medical profession. One reason why the medical services have worked with remarkable efficiency is the experience gained less than a score of years ago in Finland's war of liberation. It was, in a certain sense, a rehearsal for the present war. The fighting in 1918 was a mere skirmish compared with the pitched battles of today, but all the same the systems and standards created then have made their indelible impression on the medical services in the present war. It may not be generally known that Field Marshal Mannerheim is not only in supreme command of the army in spite of being well over 70 but is also the president of Finland's National Red Cross Society.

Foreign Medical Aid

Finland has been deeply stirred by the way in which aid of almost every kind has poured into the country from abroad. Acting on the principle that he gives twice who gives quickly, the American Red Cross cabled \$16,000 during the first week of December to London for the purchase by the British Red Cross of medical supplies and anesthetics for Finland. These were immediately dispatched by air to the Finnish Red Cross, reaching Helsinki within a few hours. In their different ways, other organizations and countries have given material expression to their sympathy with the Finns. The Spanish Red Cross has sent funds for the purchase of medical supplies and for the equipment of an ambulance unit. The French Red Cross has sent motor ambulances with personnel, and Belgium, the Netherlands, Switzerland and Hungary have all made generous contributions to the common cause.

With the Foreign Ambulances

Being such close neighbors, it was natural that Sweden, Norway and Denmark should be among the first to send well equipped ambulance units to Finland. Such ambulance work is supposed to be a young man's job, so exacting are the calls on the energies of the persons concerned. But the heads of the Red Cross ambulance units from Sweden, Norway and Denmark are veterans—Prof. Gunnar Nyström and Professor Key from Sweden, Prof. Johan Holst from Norway and Professor Chievitz from Denmark. The work of these units will, however, be eased to a certain extent by a relay system, one team of surgeons and nurses being replaced by another after a certain interval. These foreign ambulance units take their orders from the Finnish high command on entering the country, and they are distributed and quartered as the Finnish authorities think fit. But these units are in matters of internal administration more or less autonomous. The larger units are usually given quarters in some important center with good road and rail communications, and from this main body the unit detaches a mobile section which establishes itself nearer the front, constituting itself an emergency hospital in a parsonage or some other comparatively spacious building.

The Swedish Ambulance Services

The first Swedish ambulance service reached Finland on the morning of December 22 by sea, Professor von Törne greeting it at Aabo on behalf of the Finnish Red Cross. It proceeded thence by rail to Helsinki and is now established "somewhere in Finland." The school building taken over by this unit is provided with 150 beds. While the first unit had a staff of only forty, the second unit has a staff of 127, including twenty-one doctors. This second unit will be able to deal with 250 bed cases at a time. Some of its vehicles are of a new type,

designed by a civil engineer, Harald Ekman, who is in charge of the technical section of the Stockholm fire department. Both units have their own kitchens on wheels, and their equipment is such that they can still carry on even if food supplies from without run short and the electric current is cut off. Provision has also been made for lack of housing accommodation, the units having brought their own tents and huts equipped with their own heating apparatus and the outfit of a primitive operating room. Such independence of extraneous aid is most necessary in a war dominated in the air by bombers only too apt to be color-blind at the sight of a red cross, be its color ever so vivid, or its dimensions ever so large.

The Nature of the Casualties

So far this has been a war of high explosive and incendiary bombs, not a gas war. Doubtless meteorologic considerations rather than any tenderness of conscience in a humanitarian sense have relegated gas to the background, and for this immunity there is every reason to rejoice. But high explosives are bad enough, as shown by the report of Prof. Johan Holst, who has been at work near the front for several weeks and whose experience of war surgery in Finland's war of liberation and at the western front with the German forces in the war of 1914-1918 gives him a perspective in his observations of the present war. He reports that the wounds he has dealt with have on the whole been unusually severe, and he has found that just on this account the consumption of surgical dressings has been seven or eight times greater than in a civilian hospital of the same dimensions in time of peace. Another factor with a profound influence on the character of many of the casualties is the low temperature at this time of the year. Indeed, many of the casualties are exclusively due to prolonged exposure to severe cold. On the southern front the war during the first two months has been of a stationary character, with the Finns, at any rate, well entrenched. But on the eastern and northern fronts the opposing forces have surged backward and forward over wide areas sparsely populated—conditions profoundly altering the circumstances under which wounds are inflicted and treated.

A Tower of Babel

In time of peace, Finland is a bilingual country, Finnish being spoken by the masses, Swedish by the classes. The Danish and Norwegian doctors and nurses understand the Swedish spoken by the Finns and so are at an advantage compared with the ambulance units coming from other countries. The Swedish ambulance units have taken the precaution to include in their personnel people who speak both Finnish and Russian. But even so, the language difficulty is a serious problem.

SWITZERLAND

Antivivisection Defeated in Basel

In Basel a campaign against vivisection recently came to a close. The antivivisectionists had forced a vote by submitting the necessary 10,000 signatures required for the popular initiative. The campaign created great excitement in Switzerland and beyond its borders. The representative of the government of Basel, which has jurisdiction over educational and university affairs, pointed out that experimentation on animals was a scientific necessity, since the efficacy of new pharmaceutical remedies could not be tried out at once on human beings. The agitation of the antivivisectionists had a special significance for Basel with its highly developed pharmaceutical industry. The acceptance of the popular initiative would have necessitated removal of at least a part of this industry. The action of the council in rejecting it (ninety-seven to one) pointed the way to its defeat at the polls. Since the opponents of vivisection

32637

had smuggled into their bill other measures, scientific experimentation such as injections would have been killed if it had been adopted.

The defeat of the popular initiative proposal had been preceded in Basel by an intensive medical campaign to educate the public and clarify popular misconceptions. The *Schweizerische medizinische Wochenschrift* had issued a special number in which vivisection was discussed from the points of view of physiology, pharmacology, hygiene, psychology and clinical and veterinary practice. The fight against the antivivisectionists was conducted with great skill and veered from the defensive to the offensive by exposing the weaknesses inherent in the arguments of the proponents and the inconsistencies in their attitude. The indispensability of the technic of scientific experimentation on animals was vigorously maintained.

It was pointed out that what the vivisectionists charged might have occurred formerly and might still be found sporadically but did not exist in Switzerland either at Swiss university institutes or in the laboratories of the pharmaceutical laboratories. Besides, since 1934 an agreement between the assembly of delegates of the German Swiss societies for the protection of animals and the Swiss society of medical biology had formulated principles of control. This had been concealed by the militant antivivisectionists. According to these principles, accepted by both organizations, animal experimentation could be performed only if absolutely necessary and was confined within narrow limits. Experiments were to be performed as much as possible on the lower animals first. Dogs were to be used only when other kinds of animals could not be substituted. Other mammals of the higher order were similarly protected. Narcosis was to be practiced on animals in the same way as in man. Besides, animal experiments could be carried out only in institutes under responsible scientific management and subject to state control. They were permitted for purposes of classroom instruction only if they could not adequately be replaced by other methods of demonstration. All institutes performing experiments on animals as well as the laboratories of the pharmaceutical industry, it was stressed, were governed by these principles. In consequence, "animal torture in the name of science" did not occur in Switzerland.

Hediger, of Berne, set forth, in the special issue referred to, that the opponents of vivisection had no right to pretend to be experts in matters of animal experimentation. They lacked the necessary knowledge of biology and animal psychology. Their opposition rested basically on egocentric ideas. All questions pertaining to the protection of animals and vivisection could be determined, he said, only on the basis of scientific biology. No doubt sentiment played a part in the attitude of those who opposed vivisection, rooted, perhaps, in a deep feeling of the need of animal companionship in the absence of normal human relationships.

The proposal of the antivivisectionists was rejected by a vote of 18,987 to 5,036; only half of the original petitioners voted in the affirmative, seemingly a proof of the value of medical campaigns for educating the public. The society for the protection of animals publicly opposed the popular initiative.

Obituary

Prof. Fritz de Quervain, for many years a surgeon in Berne, died at the age of 71 after a brief illness. He had studied in Berne under Theodor Kocher and with Kocher published an encyclopedia of surgery in 1902. He became director of the surgical division of the hospital in la Chaux-de-Fonds. In 1909 he was appointed professor of surgery at the University of Basel. In 1918 he succeeded Kocher at the University of Berne and as director of the surgical clinic and served there many years. Not long ago he retired. De Quervain specialized in the field of thyroid gland diseases but was conversant with nearly all fields of clinical surgery. His "Special Sur-

gical Diagnosis" appeared in 1907 and was repeatedly revised and was translated into English, French, Italian, Spanish and Russian. De Quervain was highly esteemed, an excellent teacher, an experienced clinician and a man of charming personality.

ITALY

(From Our Regular Correspondent)

Jan. 15, 1940.

Congress of Radiology

The fourth Italian Congress of Radiology was held at Turin. Professor Meldolesi discussed the physical and biologic doses in measuring energy from ultraviolet sources. In heliotherapy and phototherapy the threshold of cutaneous erythema is the unit of biologic measure in actinology. In measuring ultraviolet energy by physical doses an agreement for the proper unit has not been reached. The ionometric method cannot be applied, the photochemical methods give uncertain results and the photoelectric methods, although sensitive, are inconvenient.

Professor Stoppani discussed the absorbed and transformed doses in irradiations of high potency. Increase of voltage results in percental increase of the dose, which, however, is not proportional to the increase of tension. Increase of tension, filtration and distance improves the condition of the physical factors. It makes it possible to apply radiation to lesions located in certain spots on which the application of radiation by the common technic is difficult.

Professor Castaldi spoke on the development of knowledge of mitogenic (Gurvich) rays. Studies show that tissues of living persons may give off ultraviolet radiations which originate in the tissues during reactions of oxidation and reduction, proteolysis, glycolysis, lipolysis and some other reactions. The wavelength of the radiations varies from 1,900 to 2,500 angstroms.

Professor Gallavresi studied the curve of mitosis in irradiated tumors. He found that shortly after the irradiating is begun typical karyokinesis prevails over atypical mitosis and that both typical and atypical mitosis diminish. The diminution is followed by a transient increase of atypical mitosis and then by a progressive lowering of karyokinesis, which entirely subside when the tumors are favorably modified by the treatment.

Professor Epifanio discussed the biologic and therapeutic action of neutrons on tumors. He found that hyaline degeneration and pyknosis caused by neutrons are more intense and of greater extension than those from gamma rays and that the neutronal treatment is followed by production of stromal reactions in abundance.

Deaths

Prof. Agenore Zeri, emeritus professor of medical special pathology at the Rome University, is dead. He was a professor in Italian universities for forty-two years.

Marriages

WALTER DOUGLAS HANKINS, Johnson City, Tenn., to Miss Helen Calvert Moyler of Franklin, Va., January 27.

ALGOT ASTROM, Harrodsburg, Ky., to Miss Rena May Wolcott, South Carrollton, in Lexington, January 18.

HOWARD M. SAPIRO, West Scarborough, Maine, to Miss Edythe R. Tavel of Worcester, Mass., Oct. 22, 1939.

CHARLES HATHORN WHEELER JR. to Miss Harriet Antoinette Winslow, both of New York, January 20.

THOMAS H. KUHNERT, Bristol, Tenn., to Miss Shirley Fisher of Franklin, Va., recently.

HUGH G. BOYLE, Wilkes-Barre, Pa., to Miss Marion Quigley of Luzerne, Dec. 28, 1939.

PAUL MITCHELL GLENN to Miss Hortense McClellan, both of Cleveland, January 20.

ELMER J. TEAGARDEN, Orlando, Fla., to Mrs. Mabel Barry of Apopka, January 17.

Deaths

Baxter L. Crawford ☉ Philadelphia; University College of Medicine, Richmond, Va., 1912; assistant professor of pathology at Jefferson Medical College of Philadelphia; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; served during the World War; on the staff of the Jefferson Hospital; aged 53; died, January 3, at the White Haven (Pa.) Sanatorium, of pulmonary tuberculosis.

David Daniel Swearingin ☉ Roswell, N. M.; Fort Worth (Texas) School of Medicine, Medical Department of Fort Worth University, 1901; member of the House of Delegates of the American Medical Association in 1919; on the staff of the St. Mary's Hospital; past president of the Chaves County Medical Society; aged 72; died, January 15, of coronary thrombosis.

Leroy Elijah Belding, St. Charles, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1912; member of the Missouri State Medical Association; formerly county coroner; aged 50; on the staff of St. Joseph's Hospital, where he died, January 30, of embolism following a fracture of the leg received in a fall.

John Francis Crosby, Seneca Falls, N. Y.; University of Vermont College of Medicine, Burlington, 1883; member of the Medical Society of the State of New York; past president of the Seneca County Medical Society; formerly member of the state legislature and mayor of Seneca Falls; aged 81; died, January 2, of chronic arthritis.

Charles Joseph Kane, Paterson, N. J.; Columbia University College of Physicians and Surgeons, New York, 1899; member of the Medical Society of New Jersey; fellow of the American College of Surgeons; aged 66; on the staff of St. Joseph's Hospital, where he died, January 16, of laryngeal edema, arteriosclerosis and chronic arthritis.

Larkin Hamilton Jennings, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1900; past president and secretary of the Lee County Medical Society; at one time mayor of Bishopville; for many years member of the board of trustees of his alma mater; aged 66; died, January 28, in the Providence Hospital.

Elmer Jefferson Bissell, Santa Barbara, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1883; fellow of the American College of Surgeons; member of the board of directors from 1926 to 1936 and president of the board from 1927 to 1931, Santa Barbara Cottage Hospital; aged 78; died, January 4.

W. Levell Draper, Niagara Falls, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1890; University of Buffalo School of Medicine, 1899; formerly mayor; for many years county coroner; on the staff of the Mount St. Mary's Hospital; aged 74; died, January 26, of a fracture received in a fall, and arteriosclerosis.

Charles Herbert Borden, Summit, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; at one time health officer of Stamford, Conn.; aged 66; died, January 27, in the James M. Jackson Memorial Hospital, Miami, Fla., of injuries received when he was struck by an automobile.

James Allen Clevenger, Garrett, Ind.; University of Nashville (Tenn.) Medical Department, 1888; member of the Indiana State Medical Association; at one time mayor and secretary of the board of health; secretary of the school board; aged 79; died, January 28, in Fort Lauderdale, Fla., of coronary occlusion.

Arthur Ginnever, New York; New York Homeopathic Medical College and Hospital, New York, 1901; member of the Medical Society of the State of New York; aged 74; died, January 28, in the Northampton-Accomac Memorial Hospital, Nassawadox, Va., of injuries received in an automobile accident.

C. Fred Webner ☉ Newark, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; on the staff of the Hospital of St. Barnabas and for Women and Children and the Newark Eye and Ear Infirmary; aged 71; died, January 28, of coronary occlusion.

Hugh Lawson Peters, Knoxville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1911; member of the Tennessee State Medical Association; served during the World War; on the staffs of the Knoxville General and Fort Sanders Hospitals; aged 55; died, January 28, in St. Mary's Hospital.

Lowry W. Page ☉ Buckhannon, W. Va.; Eclectic Medical Institute, Cincinnati, 1909; past president of the Upshur County Medical Society; formerly county health officer and member of

the county board of education; on the staff of St. Joseph's Hospital; aged 67; died, January 12, of carcinoma of the colon.

Leon Clemmer, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1912; professor of obstetrics at his alma mater; fellow of the American College of Surgeons; served during the World War; obstetrician to the Hahnemann Hospital; aged 51; died, January 8, of chronic myocarditis.

David Sylvester Conley, Streator, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; member of the Illinois State Medical Society; at one time president of the city board of health; aged 79; died, January 24, of chronic interstitial nephritis.

P. Clinton Pumyea ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1905; on the staff of the Welfare Hospital; formerly on the staff of the Central and Neurological Hospital; aged 59; died, January 18, of coronary thrombosis.

Robert Clayton Buck, St. Johns, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; served during the World War; formerly surgeon in the U. S. Public Health Service reserve; aged 66; died, January 26, of cirrhosis of the liver.

Albert Frederick Kaeser ☉ Highland, Ill.; University of Illinois College of Medicine, Chicago, 1901; served during the World War; at one time bank president; on the staff of St. Joseph's Hospital; aged 61; died, January 28, in the Barnes Hospital, St. Louis.

Samuel C. Trippe, Royal Oak, Md.; University of Maryland School of Medicine, Baltimore, 1875; member of the Medical and Chirurgical Faculty of Maryland; aged 90; died, January 24, in the Emergency Hospital, Easton, of a hip fracture received in a fall.

Arthur Franklin Stotts ☉ Galesburg, Ill.; Medico-Chirurgical College of Philadelphia, 1899; fellow of the American College of Surgeons; served during the World War; on the staff of the Galesburg Cottage Hospital; aged 64; died, January 9, of angina pectoris.

William Denney Hoffecker, New Canaan, Conn.; Hahnemann Medical College and Hospital of Philadelphia, 1908; aged 56; on the staff of the Norwalk (Conn.) General Hospital, where he died, January 1, of pulmonary embolism following prostatectomy.

Hugh Arthur Barbee ☉ Point Pleasant, W. Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; past president of the Mason County Medical Society; aged 65; died, January 29, in the Holzer Hospital, Gallipolis, of meningitis.

Arthur Rhodes Bradbury, Grand Island, N. Y.; University of Buffalo School of Medicine, 1892; member of the Medical Society of the State of New York; for many years health officer; aged 70; died, January 12, of injuries received in an automobile accident.

Roy Andrew Dodge ☉ Omaha; Medical Department of Omaha University, 1901; at one time secretary of the Omaha-Douglas County Medical Society; on the staff of the Douglas County Hospital; aged 62; died, January 19, of cirrhosis of the liver.

Edmund Charles Boddy, Oil City, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; served during the World War; resident physician to the Grand View Institution; aged 65; died, January 12, of heart disease.

Charles Rasmi Christenson ☉ Starbuck, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; on the staff of the Minnewaska Hospital; aged 72; died, January 14, in the Morris (Minn.) Hospital of gastric ulcer.

Edward Louis Burns, Newark, N. J.; Harvard Medical School, Boston, 1890; member of the Medical Society of New Jersey; aged 74; on the staff of St. James Hospital, where he died, January 29, of arteriosclerosis and right hemiplegia.

Robert Bruce Armstrong ☉ Charlevoix, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; at one time mayor; on the staff of the Charlevoix Hospital; aged 73; died, January 30, of coronary occlusion.

James Moreau Brown ☉ Jersey City, N. J.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; aged 62; died, January 30, in the Medical Center of Jersey City of lobar pneumonia.

John Leroy Fisher, Owego, N. Y.; Jefferson Medical College of Philadelphia, 1894; member of the Rhode Island Medical Society; served during the Spanish-American and World wars; aged 76; died, January 27, of chronic myocarditis.

Ernest Anthony Everett, O'Fallon, Ill.; St. Louis University School of Medicine, 1906; member of the Illinois State Medical Society; aged 56; died, January 19, in St. Elizabeth's Hospital, Belleville, of coronary thrombosis.

Robert Dewar MacKenzie ♂ Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1914; served during the World War; aged 48; died, January 28, of injuries received in an automobile accident.

Rupert Clyde Priest, Rusk, Texas; Southwestern University Medical College, Dallas, 1910; member of the State Medical Association of Texas; aged 59; died, January 23, in a hospital at Jacksonville of cardiorenal disease.

John Turner Kendall, Argos, Ind.; Hospital Medical College of Evansville, Ind., 1885; Rush Medical College, Chicago, 1886; aged 75; died, January 30, in the Parkview Hospital, Plymouth, of intestinal obstruction.

Frederick William Stoermann, Kansas City, Mo.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1894; aged 75; died, January 14, in the Research Hospital of pulmonary infarction.

George Francis McIntire ♂ West Barrington, R. I.; Harvard Medical School, Boston, 1908; member of the Massachusetts Medical Society; aged 68; died, January 9, in the Jane Brown Memorial Hospital, Providence.

Guy Ransom Fromm ♂ Cincinnati; Eclectic Medical College, Cincinnati, 1916; on the staff of the Booth Memorial Hospital, Covington, Ky., and the Deaconess Hospital; aged 54; died, January 31, of carcinoma.

Hiram Ferdinand Datesman, Passaic, N. J.; New York Homeopathic Medical College and Hospital, New York, 1899; for many years on the staff of St. Mary's Hospital; aged 88; died, January 31, of senility.

Archie Kelly Higgs, Portland, Ore.; Arkansas Industrial University Medical Department, Little Rock, 1891; state senator; served during the World War; aged 68; died, January 19, of coronary occlusion.

George Merriman Burrall, Los Angeles; University of California Medical Department, San Francisco, 1923; member of the California Medical Association; aged 42; died, January 14, of cirrhosis of the liver.

John Anderson, Cleveland; Niagara University Medical Department, Cleveland, 1895; on the staff of the Polyclinic Hospital; aged 78; died, January 23, of arteriosclerotic heart disease and bronchopneumonia.

Adolph Widder, Cleveland; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1896; served during the World War; aged 65; died, January 20, of coronary thrombosis.

Robert B. Campbell, Franklin, Neb.; Keokuk (Iowa) Medical College, 1894; member of the Nebraska State Medical Association; aged 69; died, January 22, of arthritis, endocarditis and arteriosclerosis.

Allton Lawrence Sherman ♂ Orange, N. J.; Yale University School of Medicine, New Haven, Conn., 1914; on the staff of St. Mary's Hospital; aged 50; died, January 9, of coronary thrombosis.

George Alvin Holland ♂ Newark, N. J.; University of Vermont College of Medicine, Burlington, 1930; on the staff of the Beth Israel Hospital; aged 39; died, January 4, of acute coronary occlusion.

Henry B. Downs, Danville, Ill.; St. Louis College of Physicians and Surgeons, 1898; formerly a minister and lawyer; aged 80; died, January 21, in the Lake View Hospital of chronic myocarditis.

William Nathaniel Hankins, Shreveport, La.; University of Tennessee College of Medicine, Memphis, 1915; served during the World War; aged 49; died, January 30, of ventricular fibrillation.

Chauncey C. Hacker, Elizabethton, Tenn.; College of Physicians and Surgeons, Baltimore, 1907; formerly mayor; aged 63; died, January 14, of coronary thrombosis and arteriosclerosis.

Lee M. Clarke, Pelahatchee, Miss.; University of Tennessee Medical Department, Nashville, 1891; aged 74; died, January 8, of multiple sclerosis and bronchopneumonia.

Harriet Agnes Williams Baker, Pittsfield, Mass.; Boston University School of Medicine, 1903; aged 61; died, January 7, in Boston, of carcinoma of the stomach.

Henry Charles Kehoe, Fort Myers, Fla.; Pulte Medical College, Cincinnati, 1885; aged 82; died, January 1, in Shelbyville, Ky., of cerebral hemorrhage.

Jonathan Howard McCaleb, New Orleans; College of Physicians and Surgeons, Baltimore, 1881; aged 84; died, January 7, in the Touro Infirmary.

Francis Eugene Prestley, Mexico, D. F., Mexico; Rush Medical College, Chicago, 1893; aged 68; died, January 23, of pneumonia following an operation.

Charles Raymond Farnham, Milwaukee; Milwaukee Medical College, 1904; aged 60; died, Dec. 9, 1939, of coronary sclerosis and chronic myocarditis.

Clara C. Sterling, Chicago; Hering Medical College, Chicago, 1907; aged 71; died, January 4, in the Middle Georgia Hospital, Macon, of myocarditis.

John Ellsworth Holland, Mount Pleasant, Iowa; Bellevue Hospital Medical College, New York, 1890; aged 77; died in December 1939 of heart disease.

Benjamin Harvey Hill Ward, Atlanta, Ga.; Atlanta School of Medicine, 1908; aged 55; died, January 22, of heart disease and chronic nephritis.

Mert Hawkins Starnes, Lubbock, Texas; University of Texas School of Medicine, Galveston, 1916; aged 50; died, January 20, of pneumonia.

Frank D. Kelly, Olanta, S. C.; Medical College of the State of South Carolina, Charleston, 1911; aged 52; died, January 7, in a hospital at Florence.

Walter W. Bruce, Portland, Ore.; Willamette University Medical Department, Salem, 1902; aged 60; died, January 9, of coronary thrombosis.

Donald Stevens Adams ♂ Los Angeles, Calif.; Harvard Medical School, Boston, 1933; aged 34; died, Dec. 4, 1939, of chronic myocarditis.

Charles T. Black, El Dorado, Ark.; Memphis (Tenn.) Hospital Medical College, 1906; aged 57; died, January 26, of chronic myocarditis.

Karl Campbell Prichard ♂ Huntington, W. Va.; Jefferson Medical College of Philadelphia, 1906; aged 60; died, January 5, of pneumonia.

Newton Cook, Sandy Creek, N. Y.; University of the City of New York Medical Department, 1879; aged 85; died, January 7, of pneumonia.

William Albion Dulaney, Wayne City, Ill.; St. Louis University School of Medicine, 1905; aged 66; died, January 21, of myocarditis.

Milo A. Schultz ♂ Memphis, Tenn.; Memphis Hospital Medical College, 1902; aged 63; died, January 18, of chronic myocarditis.

James B. Dunham, Wenona, Ill.; Hahnemann Medical College and Hospital, Chicago, 1881; aged 85; died, January 10, of myocarditis.

Guy Wimberly ♂ Ringgold, La.; Memphis (Tenn.) Hospital Medical College, 1908; aged 57; died, January 16, of chronic myocarditis.

Oscar Clarence McCarn, Warrior, Ala.; Birmingham Medical College, 1907; aged 62; died, January 15, of coronary thrombosis.

Mark Alva Nye, Omaha; University of Nebraska College of Medicine, Omaha, 1904; aged 67; died, January 21, of coronary occlusion.

Charles E. Howard, Benton, Ky.; University of Louisville Medical Department, 1892; aged 74; died, January 23, of myocarditis.

Charles R. Sheckler, Brokenword, Ohio; Columbus Medical College, 1878; aged 83; died, January 7, of arteriosclerosis.

Clarence H. Adye, Newtonville, Ind.; Louisville (Ky.) Medical College, 1894; aged 69; died, January 13, of myocarditis.

John Pedden, Grand Rapids, Mich.; Detroit College of Medicine, 1900; aged 67; died, January 18, of bronchopneumonia.

Franklin J. Patchin, El Paso, Texas; Columbus Medical College, 1881; aged 87; died, January 1, of chronic nephrosis.

Frank Oliver Wood, Hope, Ark. (licensed in Arkansas in 1903); aged 77; died, January 12, of cardiorenal disease.

William P. Leonard ♂ Talbotton, Ga.; Atlanta College of Physicians and Surgeons, 1900; aged 63; died, January 20.

Eli Trimble, Seymour, Mo.; Louisville (Ky.) Medical College, 1896; aged 73; died, January 5, of diabetes mellitus.

William A. Wilson, Gahanna, Ohio; Columbus Medical College, 1878; aged 85; died, January 22, of carcinoma.

Mike Hodge Pearce, Elko, Ga.; Atlanta Medical College, 1914; aged 56; died, January 20, in Hawkinsville.

Correspondence

COMPULSORY SICKNESS INSURANCE

To the Editor:—The industrial picture in Britain has lately been holding my attention because it is the nation whose experience with compulsory health insurance that has been presented as most worthy of being copied.

Prior to the rearmament activity, Britain's unemployed were listed as approximating 2,000,000. In spite of the war's effect on employment it is said to have been 100,000 more in December 1939 than in the preceding September.

Up to the time of the initiation of rearmament the recipients of the dole were estimated to be in the neighborhood of from 16 to 18 million. How are the figures relative to the unemployed to be correlated with those on the dole?

Half of Britain's working population receives less than £250 (\$1,250) annually. These and their dependents—again, a matter of 18 million—are the beneficiaries of her National Health Insurance. What relation have their numbers to the unemployed or to those on the dole? If the figures for those on the dole do not represent the same fraction of the population as the employed group with incomes less than £250, how, then, are their health needs met? Are they the "charity" of the profession or, if not, in what manner do they provide or is compensation provided for the physician?

Physicians in Britain receive 9 shillings (\$2.25) per capita annually. Yet it is proposed in California, among one fifth as many beneficiaries, for one half as many physicians to give the latter more than two times as much as is allotted to their colleagues in Britain under an identical taxation scheme.

JOHN F. QUINLAN, M.D., San Francisco.

"GERIATRICS"

To the Editor:—Permit me to correct an error in Dr. Tuohy's article on geriatrics in your issue of January 20. He said "Masters introduced it (the word 'geriatrics') in a thesis in 1914." I coined the word "geriatrics" and suggested it to cover a special branch of medicine dealing with old age, in a paper which appeared in the *New York Medical Journal* Aug. 21, 1909, lectured on Geriatrics in Medical Schools in Chicago, New York and Boston from 1909 to 1916, organized the New York Geriatric Society in 1912, and Blakiston published the first edition of my textbook "Geriatrics, Diseases of Old Age and Their Treatment" in 1914. Official duties prevented the continuance of my work in geriatrics. Now, retired and well along in years (76), I still take an active interest in the subject and hope to see it become a major branch of medicine.

I. L. NASCHER, M.D., Port Richmond, N. Y.

TREATMENT OF WAR FRACTURES BY THE CLOSED METHOD

To the Editor:—In *THE JOURNAL*, February 10, in the London letter there appears under the caption "Treatment of War Fractures by the Closed Method" a discussion of a report by Dr. Trueta before the Royal Society of Medicine. In this report is described a method of treating compound fractures which one would gather is supposed to be something new. According to the London letter, in the discussion "the president of the section of surgery, Mr. Cope, described it as momentous and bidding fair to revolutionize a most difficult war problem."

The mechanical disinfection-closed plaster cast treatment of compound injuries has been well known and widely used in this country since its description by H. Winnett Orr, of Lincoln, Neb., and since the publication of Orr's book (*Osteomye-*

litis and Compound Fractures, St. Louis, C. V. Mosby Company, 1929) it has been adequately described in a number of places (Bickham, W. S., and Smyth, C. M., Jr.: *Operative Surgery*, Philadelphia, W. B. Saunders Company, 1933, vol. 7; Warbasse, J. P., and Smyth, C. M., Jr.: *Surgical Treatment*, Philadelphia, W. B. Saunders Company, 1937, and in a number of papers by Damon B. Pfeiffer and myself). It would seem, therefore, that the so-called revolutionizing of this problem has been somewhat delayed in other parts of the world. Is it possible that this is another illustration of that well known British frugality in giving credit to anything originating in America?

CALVIN M. SMYTH JR., M.D., Philadelphia.

"SAFE TRANSPORT FOR THE UNCONSCIOUS PATIENT"

To the Editor:—I read Dr. Flagg's communication on "Safe Transport for the Unconscious Patient" in *THE JOURNAL*, February 17, with great interest because only last week I encountered a very similar case.

At 5 p. m. on February 14 I was called to see a married woman aged 28 who was sinking rapidly. Forty hours previously she presented symptoms and signs plus spinal fluid changes of a subarachnoid hemorrhage, and since that time she had been semiconscious, rousing at intervals. When I arrived at the home her husband was applying artificial respiration, there being no voluntary effort; her radial pulse was barely felt at 120 and her heart sounds were feeble. A lumbar puncture was immediately done and circulatory stimulants were given. An ambulance was called and arrangements were made to place the patient in a Drinker respirator in a Syracuse hospital. The ambulance arrived at 8:15 and the patient was placed in it and, escorted by state police, carried a distance of 35 miles through a blinding snowstorm to the hospital, which was reached at 10:45. All this time artificial respiration was being maintained by four persons taking turns in the ambulance. The patient was immediately placed in the respirator after being placed on a hospital stretcher and taken upstairs in an elevator; she survived for three hours in it. Autopsy confirmed the diagnosis, there being a rent in an aneurysm of the right middle cerebral artery on the ventral surface of the brain.

This case strengthens Dr. Flagg's statement that "the feasibility of transporting safely the patient who has ceased to breathe" really exists.

MARVIN BROWN, M.D., Cleveland, N. Y.

HYPOPARATHYROIDISM

To the Editor:—A scientific fact is unaltered by the question of its parenthood, but for the sake of historical accuracy we wish to call your attention to what appears to us to be an accidental oversight by two of your contributors. Drs. C. L. Spingarn and S. H. Geist in *THE JOURNAL* of Dec. 30, 1939, gave an able discussion of the effect of hyperparathyroidism in the mother on the developing embryo. They state that Bakwin (Tetany in Newborn Infants, *J. Pediat.* 14:1 [Jan.] 1939) called attention to the existence of hypoparathyroidism in the newborn. Permit us to say that three years before the appearance of Bakwin's publication we established by means of chemical and metabolic studies the existence of hypoparathyroidism in a 7 weeks old infant (Infantile Tetany, *Am. J. Dis. Child.* 51:816 [April] 1936). We wish to repeat that, while the question of priority may not be important, the added evidence which we presented to favor the thesis of Drs. Spingarn and Geist is of sufficient importance to merit your attention.

JOSEPH B. PINCUS, M.D.
ISAAC F. GITTLERMAN, M.D.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HODGKIN'S DISEASE AND SULFANILAMIDE

To the Editor:—I should like to ask several questions relevant to the position, if any, of sulfanilamide in the theory and therapeutics of Hodgkin's disease. I am prompted to make this inquiry by the unexpected results of the more or less unintentional use of the compound in an early case. About eighteen months ago I was consulted by a man aged 25 who gave the following history: Three months previously he had undergone the extraction of six badly infected teeth at one sitting. A few weeks later he noticed a tender lump beneath the angle of his jaw. Other lumps appeared until the cervical chain and gradually the axillary glands were enlarged, slightly painful and moderately tender to pressure. When I saw the patient, the involvement had become bilateral. The blood picture showed a moderate anemia and a slight leukocytosis (10,000), with no significant abnormalities except the presence of 4 per cent eosinophils. I removed a gland for pathologic study and, pending the arrival of the report, administered sulfanilamide in doses of from 3 to 4 Gm. daily. This was done on the concededly slim chance that, in the presence of pain and tenderness and the absence of pruritus, the adenopathy might be related to the oral sepsis described. The results were startling: the pain and tenderness, which had been present without remission since the onset, disappeared in forty-eight hours, and in the course of a week all the glands had become appreciably smaller and softer, a few becoming actually impalpable. The pathologic report, which became available at this time, described eosinophils, Dorothy Reed cells, polymorphonuclears and fibrosis, corresponding to what Jackson has since labeled the "granuloma type." The diagnosis, made by a qualified pathologist, was subsequently confirmed. Sulfanilamide therapy was discontinued immediately and the patient referred for roentgen therapy. The response to x-rays was good, and two subsequent recurrences have also responded well to irradiation. My questions are the following: Are the remissions in Hodgkin's disease frequently so dramatic that the one described may have been a coincidence, unrelated to the treatment? In the matter of the etiology of Hodgkin's disease have the theories of an infectious origin and a neoplastic response to infection gained any ground within recent years? In any case is there sufficient evidence in these directions to justify the use of sulfanilamide and related compounds, at least as an adjunct therapy, or perhaps in the intervals between courses of irradiation? If so, which of the several compounds would appear to be most suitable?

P. B. Candela, M.D., Brooklyn.

ANSWER.—The best general answer to this question is to quote from a statement made by Dr. E. B. Krumbhaar in September 1939: "Thus we see that the problems of Hodgkin's disease of the past generation remain the problems of today. We still do not know whether it is an infectious granuloma or a neoplasm, and therefore we are ignorant of its pathogenesis (its portals of entry, if any, and how it develops); we have no specific laboratory diagnostic test other than the biopsy examination; we have no means of predicting how long a given case will survive; and we have no specific form of treatment."

Remission without treatment in Hodgkin's disease is exceedingly uncommon, although progress is sometime slow. The one false note in this account is the painful and tender glands. The glands in Hodgkin's disease are usually painless and produce discomfort only by pressure on surrounding structures. No authentic report of the beneficent effect of sulfanilamide in this condition has appeared in the literature.

VISUAL SCREENING TESTS AND VISION CHARTS

To the Editor:—As a member of the board of education and president of the board of health, I have been approached by the school nurses to settle a controversy. At the National Convention of Optometrists the teachers were invited in to hear a tirade condemning the use of Snellen charts for the determination of visual acuity of school children and demanding that they use the Betts telebinocular machine. The February issue of *Hygeio* answers a question on the subject and says that a committee of the American Medical Association would soon have a report to render on the subject of the Betts telebinocular machine. Can you enlighten me by such a report? Would the routine duties of a school nurse require her to use this machine to check children's eyes on demand from the teaching organization? Is a school nurse supposed to make any diagnostic report or decision relative to a pupil's eyes? Is a teaching organization supposed to propagandize the use or sale of any optical equipment? Any help that you can give me on this subject will be doubly appreciated, in view of the fact that I am an ophthalmologist and still use Snellen charts in my own office.

M. P. Andrews, M.D., Manitowoc, Wis.

ANSWER.—The report referred to was made by the Council on Physical Therapy and was published in *THE JOURNAL* Sept. 2, 1939, page 937. The report announced that the Betts charts, which are used on the telebinocular, a form of stereoscope,

were not acceptable to the Council. This decision was made because of the experience of members of the committee that examinations with the Betts charts greatly overestimate the number of children in whom eye defects are a cause of reading disability. This opinion was supported by an investigation by Oak and Sloane, reported in the *Archives of Ophthalmology* for November 1939. The latter found that only three of 100 children were able to pass the Betts tests when repeated at two successive examinations, following the technic described in the manual. When the charts were used by another method of scoring suggested by a Keystone expert, the number of children checked as defective was still much greater than when the same children were tested by a regular ophthalmologic examination. It is true that the Snellen test reports defects only in central vision and neglects several other factors.

A series of simple tests has been arranged by Dr. Walter Lancaster and is being tried in the Boston schools and some other schools at present. These tests appear to offer advantages over both the Betts charts and the Snellen charts. The tests are made so that they can be carried out by a school nurse after a short training in their use. In most schools the school nurse is not required to make any diagnostic report but only to report that the child is or is not in need of further examination of the eyes by a specialist.

If a teaching organization demanded that a school nurse use a Betts apparatus to make a visual screening survey of the children under her charge, the nurse should refer the matter to a competent ophthalmologist, who should make it his business to set the teaching organization right about a question on which the organization lacks technical knowledge.

A school nurse is supposed to report such visual defects as her limited knowledge permits her to detect. Diagnoses and therapeutic measures lie entirely beyond the scope of her duties or capabilities. Certainly no teaching organization should propagandize the use or sale of optical equipment.

SULFANILAMIDE PROPHYLACTICALLY FOR MENINGOCOCCIC MENINGITIS

To the Editor:—Kindly advise the dosage of sulfanilamide which might be given prophylactically to children and adults exposed to epidemic cerebrospinal meningitis.

F. J. Blasingame, M.D., Whorton, Texas.

ANSWER.—Little information is available concerning the prophylactic use of sulfanilamide in infections which are susceptible to therapy with this drug. There is no published information available regarding the efficacy of the drug in the prevention of meningococcic meningitis. Unpublished reports seem to indicate that sulfanilamide therapy will not eradicate meningococci from the throats of meningococcus carriers. It is possible therefore that the prophylactic use of the drug might not be of much value in preventing meningococcic infection. However, one cannot go entirely on such data. If the drug is to be used prophylactically against meningococcic infections such use would have to be considered entirely experimental and hence the dosage required would have to be determined by the method of trial and error.

STERILE SOLUTION OF SULFANILAMIDE—SULFANILAMIDE IN ABDOMEN

To the Editor:—How can sulfanilamide be safely used in the infected abdomen, since the chemical cannot be autoclaved?

M.D., Virginia.

ANSWER.—Sulfanilamide can be autoclaved at 15 pounds pressure for five minutes without causing decomposition of the drug if it is prepared in a 1 per cent physiologic solution of sodium chloride. However, this type of sterilization is not frequently used in preparing solutions of the drug. Generally, in preparing solutions of sulfanilamide for parenteral use a measured amount of sterile physiologic solution of sodium chloride, sixth molar sodium lactate in saline solution or lactate-Ringer (Hartmann's) solution is brought to a boil and then the flame is cut off and enough crystalline sulfanilamide is added to make a 1 per cent solution. With gentle shaking the drug readily goes into solution. The solution is cooled to 37 C. and is then ready for use. Fresh solutions of the drug should be prepared daily. These solutions should be kept at room temperature. At icebox temperatures the sulfanilamide crystallizes out of solution. In these forms it could probably be used in an infected abdomen. However, experience has shown that, in general, the oral administration of the drug or its parenteral use by the subcutaneous route is preferable to using a solution of the drug as an irrigating fluid in cases of peritonitis. Ravdin and his associates (*Ann. Surgery* 111:53 [Jan.] 1940) have recently discussed

favorable results which they have obtained by the oral use of sulfanilamide in cases of acute appendicitis. In a certain proportion of these cases a localized or generalized peritonitis was present.

DIAGNOSIS AND TREATMENT OF TULAREMIA

To the Editor:—Please discuss fully the cutaneous tests for tularemia, both the test with antigen made from a diluted suspension of *Bacterium tularensis* and the test with the diluted antitularemic serum (as described in the circular which comes with Sharp & Dohme's antitularemic serum). Please discuss also the time of reading the tests, their degree of accuracy (both positive and negative reactions), and how soon after the onset of the disease they are positive. Would an agglutination reaction of patient's serum of 1:20, three years after the disease be considered evidence of tularemia in the past? What is the status at the present time of both antitularemic serum and sulfanilamide? It seems that many physicians in this vicinity are using sulfanilamide in the treatment of tularemia but I can find only one reference to its use in the *Journal*, and this is a report of only one case. In an abstract of an article by Elson from the *New Orleans Medical and Surgical Journal* of December 1938 appearing in *The Journal*, Jan. 21, 1939, page 274, it is stated that ferrous iodide is a specific in tularemia. Please elaborate.

M.D., Mo.

ANSWER:—Cutaneous tests with the special *Bacterium tularensis* antigen developed by Foshay, of the University of Cincinnati, should be read forty-eight hours after injections are made. The special antigen is safer than a highly diluted suspension made from formaldehyde-killed agglutinating antigen, since the latter is capable of provoking occasional serious focal and constitutional reactions as well as necrosing local reactions. Falsely positive reactions have not yet been recorded with Foshay's skin test antigen, and the test appears to be highly specific.

Cutaneous tests with diluted antitularemic serum must be controlled each time with equally diluted, strictly normal serum from the same animal species. Otherwise it is not possible to differentiate the bacterial-specific reaction from the serum protein-specific response. This reaction should be read immediately and at five minute intervals up to the twentieth minute. A positive reaction consists of enlargement of the central wheal to two or two and a half times its original diameter, with a surrounding areola of erythema usually at least 1 inch (2.5 cm.) in diameter, at the site of the immune serum injection, with no reaction at all at the site of the normal serum injection. Falsely positive reactions have not been recorded, and the specificity of this test appears to equal that of the cutaneous test with the bacterial antigen.

Both of these tests have given positive reactions when applied as early as eight hours after the initial chill. However, in about 7 per cent of 300 proved tularemic infections these tests were negative to initial trials in the first six days of illness (falsely negative reactions). Repetition of the tests at forty-eight hour intervals gave positive responses before serum agglutinins appeared in all persons except one. Reliability is much greater at later stages of illness.

Although the titer of 1:20 is lower than that usually found three years after illness, provided the test was performed properly and that brucellosis is not present, it may be considered that an agglutination titer of 1:20 provides evidence of previous tularemic infection.

Serum therapy has been shown to shorten morbidity and to diminish mortality to significant degrees. No accurate data are available on the use of sulfanilamide in the treatment of tularemia. Unpublished information on its use in thirty cases indicates little or no favorable action of the drug.

Since no evidence was presented to indicate that tularemic infection existed in any case mentioned in the article referred to, it is not possible from the information presented to estimate what effect syrup of ferrous iodide might have in this infection. Whenever various iodides have been administered to patients with proved tularemic infections, all students of this disease are in general agreement that there occurred no significant modifications from the natural course of the illness.

ULTRAVIOLET LAMPS

To the Editor:—Are ultraviolet lamps to be recommended for use at home for their general tonic and "sunburning" effect?

W. S. Dietrich, M.D., New Cumberland, Pa.

ANSWER:—If the object is to tan the skin and in this way obtain the sensations and perhaps the illusion that go with increased pigmentation of the skin, ultraviolet lamps can be recommended. Obtaining in this manner a general tonic effect on the body is a different matter. For many years it has been the attitude of the Council on Physical Therapy of the Ameri-

can Medical Association that ultraviolet rays generated artificially by a lamp of any kind cannot be depended on to increase the tone of tissues or of physiologic processes in general.

Exposure of the bare body to natural sunlight, especially when this is done in properly graduated periods of exposure, is often followed by an improvement in the tone and physiologic function of the skin, and indirectly of the body. However, it has never been conclusively demonstrated that this is a specific effect of the ultraviolet rays produced by the sun. There is evidence to indicate that the mere contact of the skin with the open air plays a part in these effects and it is not clear, therefore, how much of these effects are due to contact with open air and how much may be attributed to the direct action of the ultraviolet rays from sunlight.

Ultraviolet rays produced artificially by various kinds of lamps only remotely simulate the spectrum of sunlight. Such a beam of ultraviolet rays is made up chiefly of certain lines of the spectrum where the intensity is high, but at other points in the spectrum the intensity may be low or absent. It is for this and the other reasons mentioned that the Council has not allowed manufacturers of accepted ultraviolet generators to advertise that exposure to rays generated by their lamps increases the tone of tissues or of other body structures.

FLUORIDES AND MOTTLED ENAMEL

To the Editor:—In the particular locality where I am practicing the drinking water contains fluorine, 3 parts per million; this amount is definitely enough to mottle the teeth in children who drink it. The question arises, and I have been asked many times: 1. Is it necessary for a pregnant or nursing mother, in order to prevent mottling of her child's teeth, to seek water with a lesser concentration of fluorine? 2. Is it possible that fluorine ingested at that time could mottle the teeth later? 3. Would it be possible that enough fluorine could be obtained from pasteurized milk of local cows to cause mottling?

M.D., Arizona.

ANSWER:—1. It is unlikely that the use by a mother during the period of gestation and lactation of a domestic water containing 3 parts per million of fluorides will result in the mottling of her child's teeth. This statement is based on epidemiologic evidence. In endemic areas where the fluoride concentration is considerably higher than the quantity referred to, only sporadic instances of mottled enamel are observed in the deciduous teeth. A considerable portion of the calcification of the deciduous teeth occurs in utero; probably this explains their relative freedom from mottled enamel.

2. It should be borne in mind, however, that certain of the permanent teeth begin calcification of the crowns at birth or shortly thereafter. Water containing 3 parts per million of fluorides would produce mottled enamel in a high percentage of those children using it for drinking and cooking during the calcification period. For instance, the calcification of the crowns of the permanent central incisors begins between the third and fourth months of life and is completed between the fourth and fifth years. It is during this period that the toxic effects of fluorides with respect to mottled enamel are operative even though these teeth do not erupt until several years later. For the protection of all permanent teeth, third molars excepted, the fluoride content of the water used for both drinking and cooking during the first eight years of life should not exceed 1 part per million.

3. Phillips, Hart and Bohstedt (*J. Biol. Chem.* 105:123 [April] 1934) state that no difference was observed in the biologic reaction of rats fed normal milk as compared with those fed milk from cows receiving an added source of fluorine. They further note that the fluorine content of milk is comparatively difficult to influence by dietary means.

IRON IN MOLASSES, TABLE SYRUPS AND SUGARS

To the Editor:—Recently I heard over the radio a food "expert" speak about molasses containing a large amount of iron. I thought molasses was a sugar just like corn syrup. How much iron is in molasses, honey, karo syrup and dextrinmaltose? Has molasses been used in infant feeding formulas? If so, with what results?

M.D., New York.

ANSWER:—Molasses as formerly manufactured was the mother liquor remaining after the removal of one crop of sugar crystals from the boiled down juice of the sugar cane. Because the removal of cane sugar by one crystallization is far from complete, the molasses thus obtained was rich in sucrose. It also contained the majority of the other constituents of the cane juice, including the ash, in relatively high proportion. It is now customary to remove the sucrose more nearly completely by a series of crystallizations. Types of molasses derived from successive crystallizations of sugar are designated as first, second and third molasses; they differ from one another in sucrose and ash content, the first molasses containing more

sucrose and less ash than the second or third. The iron content of the molasses products of one manufacturer has been determined by Harris, Mosher and Bunker (*The Nutritional Availability of Iron in Molasses, Am. J. Dig. Dis. 6:459* [Sept.] 1939), who found a content of 3.2, 6.0 and 11.3 mg. of iron per hundred grams respectively for first, second and third molasses. Other investigators have reported an average iron content of 7.3 mg. per hundred grams, or 0.0073 per cent. The iron of molasses is reported to be in available form, although that of the third molasses appears less well utilized by rats than that of the first and second types. Molasses may be considered a rich and inexpensive source of iron in the diets of older children and adults. No reports of the use of this product in infant feeding have appeared in the scientific literature.

Most table syrups used as modifiers of milk in infant feeding are prepared from corn syrup and either sugar syrup or refiners' syrup. The corn syrup ingredient is prepared by hydrolyzing corn starch in an acid solution under steam pressure until a definite percentage of dextrose is formed. The solution is then neutralized with sodium carbonate and filtered. The filtrate is concentrated in vacuum to the desired density. Refiners' syrup is the mother liquor or residual product obtained in the process of refining substances which distinguish the brown or yellow raw cane sugar from the white refined cane sugar. According to federal definition, refiners' syrup contains not more than 25 per cent water and not more than 8 per cent ash. Sugar syrup is the product made by dissolving cane or beet to the consistency of the syrup. It contains not more than 35 per cent water. In general, the light table syrups containing corn syrup consist of a mixture of corn syrup and sugar syrup, and the dark or "golden" syrup consists of corn syrup flavored with refiners' syrup. According to Rose (*Laboratory Handbook for Dietetics, ed. 4, New York, Macmillan Company, 1937*), dark corn syrup contains an average of 12.8 mg. of iron per hundred grams while the light corn syrup contains about 1.4 mg.

Schuette and Remy (*J. Am. Chem. Soc. 54:2909, 1932*) have studied the iron content of honey and report that light honeys contain an average of 0.24 mg. of iron per hundred grams while dark honeys contain an average of 0.94 mg. A maximum value of 3.5 mg. was reported for dark honeys. No information concerning the iron content of dextrimaltose is available, but according to the information provided by the manufacturer and published in the book "Accepted Foods," Mead's Dextri-Maltose with Added Extract of Wheat Embryo and Yeast contains approximately 8 mg. of iron per hundred grams. Corn syrup and dextrimaltose are widely used in infant feeding, and the successful use of honey as a carbohydrate modifier for milk in infant feeding has been reported by Schlutz and Knott (*J. Pediat. 13:465* (Oct.) 1938).

NO DANGER FROM INHALING HAIR
IN DRY SHAVING

To the Editor:—Is there any possibility of damage to the lungs from inhalation of the small particles of hair cut off by dry electric shaving?
M.D., Ohio.

ANSWER.—The diameter of human hair is too great to permit successful inhalation. Investigation of the possibilities has shown that one cannot cut segments short enough to be inhaled. After prolonged attempts the project has been given up.

LEAD AND ARSENIC IN FOODS AND
PLANT SPRAYS

To the Editor:—Will you please send me the latest information you have on the human tolerance for lead and arsenic, both as obtained from spray residue on fruits and vegetables and as found naturally occurring in foods. Can you give any information regarding the possibility of plant foods absorbing lead or arsenic from soil frequently sprayed with these minerals?
Martha Potgieter, Associate Professor of Foods and Nutrition, Honolulu, Hawaii.

ANSWER.—It is not possible to summarize in any brief way the information about the human tolerance for lead and arsenic from foods. An article by H. O. Calvery (*Chronic Effects of Ingested Lead and Arsenic, THE JOURNAL, Nov. 5, 1938, p. 1722*) summarizes much of the available information and emphasizes the lack of data regarding the significance of minute traces of lead and arsenic in ordinary foods. It is known that these elements are toxic, and contamination of foods with lead and arsenic should be avoided. The present tolerance for lead and arsenic in fruits as established by the U. S. Food and Drug Administration is 3.57 parts per million for lead (as Pb) and 1.06 parts per million for arsenic (as As). These tolerances were devised with particular reference to spray residues on foods, especially apples and pears. Action can, of course, be

brought against any foods containing excessive amounts of lead and arsenic on the ground that these metals are toxic and deleterious substances. There is an interesting exception in the case of shrimp and possibly some other sea foods, in which relatively high concentrations of arsenic are found. It has been shown that this arsenic is in harmless organic combination and is not stored by the animal body but is excreted in the urine.

It is usually considered that there is a real possibility of plant foods absorbing lead or arsenic from soil which has been sprayed with large amounts of toxic insecticides containing these elements. A discussion of the subject is provided by P. J. Hanzlik (*Health Hazards of Chemo-Enemies in Contaminated Foods, Scientific Monthly 44:435* [May] 1937).

VITAMINS AND SKIN CANCER

To the Editor:—Have you any evidence that the topical application of vitamin A or vitamin D will accelerate the growth of cutaneous neoplasms, or tend to produce cancer on a normal skin or on a so-called precancerous skin?
Robert R. McLaughlin, M.D., New York.

ANSWER.—There is no published evidence that the topical application of vitamin A or vitamin D or both together will cause tumors in albino mice, the skin of these animals being much more sensitive than that of human beings. It is true that exposure of mice to considerable doses of ultraviolet radiation will cause the appearance of a few epitheliomas of the skin and attempts have been made by Roffo and others to connect the appearance of these tumors with alleged activities of cholesterol, which, of course, is present in the skin. The irradiation of cholesterol with ultraviolet rays causes the formation of some vitamin D. But no proof of this theory of cancer formation has been published. On the other hand, solutions in oil of vitamin A and vitamin D have been used by dermatologists to aid in the healing of chronic ulcerations, especially those connected with damage of the skin by x-rays. These physicians are in a position to note the production of malignant growths on a normal or a precancerous skin and as no such reports are forthcoming it is evident that neither of the substances mentioned will produce cancer on a normal skin or on a precancerous one. The increased growth rate of tumors which is occasionally observed after injury is due to the increased blood supply which feeds the tissues and enables more cells to grow.

FLUOROSCOPY AND THE DIAGNOSIS OF
MINIMAL TUBERCULOSIS

To the Editor:—In *Queries and Minor Notes* in *The Journal* January 13 (p. 180) I noticed the subject of fluoroscopy and the diagnosis of minimal tuberculosis. To supplement or perhaps amplify the information which you gave I would call attention to two articles (Fellows, H. H., and Ordway, W. H.: *Fluoroscopy versus Physical Findings in the Detection of Pulmonary Tuberculosis, Tr. Nat. Tuberc. Assn., 1937, p. 51*; *Control of Pulmonary Tuberculosis in an Employee Group: Possibilities and Limitations, ibid., p. 211*) which answer one phase of your reply having to do with the percentage of error of routine fluoroscopy as checked by roentgenograms of the chest. Also I present an abstract from our annual reports showing the percentage of new clinically significant cases picked up each year among our home office employees. It has been gratifying to detect over 75 per cent of the cases in the minimal stage during the past several years. The source of this question was also of interest to me, as one of the wholesale jobs of fluoroscopy is being carried out by Dr. Sixto A. Francisco, of Manila, who has a portable traveling fluoroscopic unit with which he has made more than 150,000 examinations. It seems to me that, until some economical and accurate method of carrying out routine case-finding studies is found, fluoroscopy fills the need. Routine roentgenograms, either on celluloid or on paper, are so expensive that, while ideal, they are unobtainable for most surveys. Certainly fluoroscopy seems to be superior to the use of physical examination and subjective symptoms in the detection of early lesions.

Tennessee Endorsement Report

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports fourteen physicians licensed by endorsement from Aug. 10 through Dec. 22, 1939. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Arkansas School of Medicine.....	(1936)		Arkansas
Atlanta School of Medicine.....	(1911)		Georgia
Emory University School of Medicine.....	(1911)		Alabama
Northwestern University.....			Michigan
University of Kansas School of Medicine.....			Oklahoma

University of Louisville School of Medicine.....	(1936)		Kentucky
Tulane University of Louisiana School of Medicine.....			Louisiana
Johns Hopkins University School of Medicine.....			Maryland

Michigan October Examination

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 11-13, 1939. The examination covered fourteen subjects and included 100 questions. An average of 75 per cent was required to pass. Thirteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1939) 78, 82,*	84†	85.6†
Rush Medical College.....	(1939)		80†
Harvard Medical School.....	(1937) 84, (1938)		78†
Wayne University College of Medicine.....	(1939) 77,*		81.5,†
Long Island College of Medicine.....	(1939)		78.5†
Temple University School of Medicine.....	(1935)		82†

Seventy-five physicians were licensed by reciprocal indorsement from Aug. 3 through Dec. 26, 1939. The following schools were represented:

School	LICENSED BY INDORSEMENT	Year Grad.	Indorsement of
University of Arkansas School of Medicine.....	(1938)		Arkansas
College of Medical Evangelists.....	(1932)		New Mexico
(1939) California, N. B. M. Ex.

Book Notices

The Dysenteric Disorders: The Diagnosis and Treatment of Dysentery, Sprue, Colitis and Other Diarrheas in General Practice. By Philip Manson-Bahr, C.M.G., D.S.O., M.D., Senior Physician to the Hospital for Tropical Diseases, London. With an appendix by W. John Muggleton, M.S.M. Cloth, Price, \$8. Pp. 613, with 129 illustrations. Baltimore: William Wood & Company, 1939.

This comprehensive work is the result of experience in the tropics and of extensive practice in the Hospital for Tropical Diseases in London. In the course of the clinical work in this hospital in the last thirty years the author has made a study of 508 cases of amebic dysentery, 423 of sprue, 107 of bacillary dysentery, 116 of mucous colitis and forty-two of ulcerative colitis, as well as many cases of other intestinal diseases. This background has afforded a rich experience and a fund of practical knowledge which has provided the material for this much needed book.

The contents fall into nine sections: introduction; bacillary, protozoal and helminthic dysenteries; infective diarrheas; steatorrheas; disorders of the colon resembling dysentery; general disorders resembling dysentery, and other causes of diarrhea and dysenteriform symptoms. Ninety-four treat of bacillary dysenteries, 133 of amebiasis and seventy-eight of sprue and related conditions.

The author stresses the necessity of sigmoidoscopy except when diagnosis is made certain by the recognition of the causative organism in the stools. The mere list of details to be inquired into in a clinical examination fills nearly three pages, with full directions for the procedures.

The historical survey records the recurrence of epidemics of dysentery in the sixth and eighth centuries A. D. and the introduction of ipecacuanha or the "dysentery root" from Brazil in the seventeenth century. Jacobus Bontius, the "grandfather of tropical medicine," described the epidemic of dysentery in Java in 1628. Sydenham, Morton and Willis distinguished between mucous evacuations and bloody flux in the great epidemic of 1668-1672 and noted the association of dysentery and arthritis. Zimmermann, who studied the epidemic in Switzerland, described (1767) the clinical varieties of dysentery. During the first half of the nineteenth century dysentery was generally regarded as but one expression of malaria, partly because of its seasonal recurrence and pandemic character. Epidemics occurred in the American colonies in 1749-1753, 1773-1777 and 1793-1798. In the epidemic of 1834-1836 in Europe it was estimated that fourteen of every thousand inhabitants perished. The dysenteries have long been associated with famine and have followed armies in all wars. A notable omission by the author in the text but not in the bibliography is that of Schaudinn's critical distinction of *Endamoeba histolytica*, which settled the futile discussion that raged from 1875 to 1903 over the pathogenicity of amebas of the human colon. Even less understandable is the omission of any reference to the extensive protozoal observations of Lewis (1870) in the examination of stools of cholera victims in India.

The discussion of amebiasis is exhaustive and thorough. Special attention is given to liver abscess and to treatment. The author is conservative in matters of treatment, adhering to the use of the drastic emetine-bismuth-iodide therapy though favor-

ing lighter doses and using it in conjunction with chinfoen enemas. He notes with regard to vioform that "he has seen several patients who appear to have been made really ill by its constant use." He rejects acetarsone except as an intestinal tonic and in the after-care of amebic dysentery on the ground that the French claims as to its value as a reliable amebicide have not been substantiated. He notes the wide use of carbarsone in the treatment of chronic amebiasis in the United States and the fact that it is less toxic than acetarsone but states that it should be administered only under supervision. The resort to surgical measures even in resistant cases of intestinal amebiasis is deprecated.

The author rejects McCarrison's dietetic deficiency and Ashford's yeast fungus as factors in the origin of sprue and regards the cause as a specific virus capable of lying dormant in the tissues for years and of being roused to activity by unknown factors. This view is supported by the definite incubation period, the patchy geographic distribution, familial occurrences, and clinical observations showing that it is a specific inflammation of the mucous membranes of the alimentary tract. Malaria and amebiasis are predisposing causes. Rest, high protein diet and palliative medicinal treatments for the various symptoms are given in detail. The discussion of the varied aspects of this disorder is a fine illustration of a comprehending view of disease and its cure.

The appendix deals with the clinical laboratory procedures in diagnosis and culture of the micro-organisms concerned in these intestinal infections. The classified bibliography of twenty-four pages contains about 1,500 entries of author and citation but usually not of titles, the omission of which robs the bibliography of much of its value, since the reader has no clue beyond the classified heading as to the content of the articles. The index is of great value in finding in this great mass of valuable data the information desired on varied subjects.

The author has rendered a great service to both physicians in general practice and to investigators of diseases of the alimentary canal and their causative organisms by this exhaustive and critical treatise.

Electrocardiographic Patterns: Their Diagnostic and Clinical Significance. By Arlie R. Barnes, M.D., Mayo Clinic, Rochester, Minnesota. Cloth. Price, \$5. Pp. 197, with 95 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, Publisher, 1940.

This monograph is an outgrowth of an exhibit which the author made and found to be extremely popular. It is a thoughtful coordination of the author's own extensive studies correlated with those appearing in the literature and, while one may not agree with all the deductions arrived at, the book definitely represents a mature consideration and will be a valuable addition to the library of every one who has to deal with electrocardiograms. As the author points out in his introduction, "the proportion of the average text on electrocardiography devoted to the arrhythmias would lead one to believe that this was still the field of its major importance. More recently, the use of the electrocardiograph to detect evidences of myocardial disease has been of major interest and importance to clinicians, and it has been possible to correlate such evidence of myocardial disease with prognosis in large groups of cases, although it is difficult to apply this knowledge to the individual patient in a group."

It is becoming increasingly apparent, primarily as the result of the efforts of American students of this subject, that the primary utility of the electrocardiogram in clinical practice rests on a study of its configuration. In this monograph the greatest stress is properly given to the appearance of the electrocardiogram in coronary disease and in myocardial infarction, but the more recently developed and growing subject of the electrocardiographic appearance in other diseases is also considered. The author discusses strains on the left and on the right side of the heart, pericarditis, infections, metabolic disorders and drugs. The last chapter is devoted to the newly developed subject of precordial leads and includes a number of summary tables of the measurements in 100 normal cases of the deflections in all the chest leads recommended recently by the Committee of the American Heart Association on the Standardization of Precordial Leads. These tables should be extremely useful to the reader in setting up the limits of normality for those chest leads which are not commonly employed.

The text is well documented with case reports, electrocardiograms and idealized diagrams. It is regrettable that the author uses the old way of depicting the direction of the deflections of the chest lead; this is upside down to that recommended by the committee, of which the author himself was a member. It is difficult to see why the author did this when it would have been easy to redraw the drawings of his records as inverted mirror images. The failure to follow the newly and universally established standard for the chest lead and the consequent use of terms in the text applicable to the lead as illustrated will be confusing to the average reader. It is hoped that in the next edition the author will take the trouble to correct this error. Confusion may also arise from the fact that various terms are applied in the text to the segment between QRS and T deflections. Nevertheless, those interested in clinical electrocardiography will find that this monograph is extremely stimulating and helpful in filling a gap by a critical assay of the recent literature on the configuration of the electrocardiogram.

Common Skin Diseases. By A. C. Roxburgh M.A., M.D., B.Ch., Physician in Charge of the Skin Department, St. Bartholomew's Hospital, London. Fifth edition. Cloth. Price, 15s. Pp. 416, with 187 illustrations. London: H. K. Lewis & Co., Ltd., 1939.

The original purpose of the author and the publishers was to provide a small compact work for the general practitioner covering the commoner skin diseases. This book deals with 120 of more than 300 skin diseases. The fact that it has already run through four editions attests its popularity. Constant revision has kept it thoroughly abreast of progress. To assist the student, an index of preliminary diagnoses has been placed at the beginning of the book to encourage him to observe accurately the type of lesion of which any given eruption is composed and to serve as a guide in looking up diseases in the book or in larger works. The various diseases are well described, briefly but adequately. Considerable emphasis is placed on differential diagnosis and treatment, and both of these are well handled. Treatment reflects the long experience of the author; it is brief but very much to the point. In this edition there are fourteen new illustrations, some notes on the new emulsifying bases, indications for administering estrogen and the therapeutic possibilities of sulfanilamide therapy. There are short new articles on the avitaminoses and granuloma annulare. The dosage of roentgen therapy is expressed in roentgens instead of pastilles. The illustrations are excellent. The text is printed with large, legible type on good paper. The book is an excellent one and if its present standard is continued it will remain a popular textbook for years to come.

Ophthalmology. By Burton Chance, M.D. XX, *Clio Medica: A Series of Primers on the History of Medicine*. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$2. Pp. 240, with 6 illustrations. New York: Paul B. Hoeber, Inc., 1939.

Bacteriology. By William W. Ford, M.D., D.P.H. XXII, *Clio Medica: A Series of Primers on the History of Medicine*. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$2.50. Pp. 207, with 8 illustrations. New York & London: Paul B. Hoeber, Inc., 1939.

These books constitute new additions to the excellent series under the general editorship of E. B. Krumbhaar.

Dr. Chance has traced the progress of ophthalmology from the earliest of written records to the present time. The nature of the eye made it particularly subject to superstitions. Thus the literature of every region is replete with notions, some of which, however, later became established as fact. After a series of chapters in which the lore of various nations is reviewed, the author gives special attention to cataract, color vision, the development of drugs and ophthalmic surgery, and finally provides concluding chapters on ophthalmic education, organizations and national development. The work is a concise summary of the history of ophthalmology.

The volume on bacteriology, by Dr. W. W. Ford, is dedicated to Dr. William H. Welch. After considering the development of knowledge concerning magnification and the work of Leeuwenhoek, he carries forward his story in chronological order through the work of Henle, Pasteur, Lister, Cohn and Koch. He reveals in his concluding chapters the manner in which immunology developed from bacteriology. The rigid bacteriology of the century has been modified and future investigations must concern themselves with the life cycle of individual types of organisms.

Primer of Allergy: A Guidebook for Those Who Must Find Their Way Through the Mazes of This Strange and Tantalizing State. By Warren T. Vaughan, M.D. Cloth. Price, \$1.50. Pp. 140, with illustrations by John P. Tillery. St. Louis: C. V. Mosby Company, 1939.

Occasionally concise treatises for the public are written on subjects of which insight and understanding are necessary for intelligent cooperation. The subject of allergy is certainly an ideal assignment for well placed literary effort, and Dr. Vaughan has done much with it. Many physicians and certainly a larger number of laymen have desired a book of this type for some time and it should be enthusiastically received. The book is so written that it can be recommended by any physician regardless of his personal approach to the subject. In fact, a book of this type placed in the hands of his patient should prove a real service to him in his practice. The text is profusely and attractively illustrated by cartoons and caricatures on allergy. It not only provides authoritative information on all phases of the subject of allergy but is written in a literary style that is both engaging and entertaining. Every physician will enjoy reading this concise and masterful message to the public and will unquestionably recommend it to his allergic patient. This is a real contribution to the layman's education in this important and complex field of medical science and deserves a place in every home where there is sneezing and wheezing.

Traité d'ophtalmologie. Publié sous les auspices de la Société française d'ophtalmologie par MM. P. Baillart, Ch. Couciola, E. Redslob et E. Veller. René Onfray: Secrétaire général. Tome III: Techniques de laboratoire, examen de la motilité et de la vision binoculaire anomalies de la vision, pathologie (début). Par MM. E. Aubaret et al. Cloth. Price, 400 francs. Pp. 1,148, with illustrations. Paris: Masson & Cie, 1939.

This volume of the new French treatise was somewhat late in making its appearance but still was under the time schedule set in the beginning. It contains laboratory technique in ophthalmology in four parts by Dubois-Poulson of Paris, Carrère of Montpellier and Senevet of Algiers, examination of motility by Nordman of Strasbourg and Onfray of Gouin, anomalies of vision, light and color sense by Joseph of Paris, Mawas of Paris, Hambreson of Brussels, Haas of Paris, Bourdier of Beaujon and Polak of Paris, and general and special pathology divided into lesions by Redslob and Gery of Strasbourg, ocular allergy by Koutseff of Strasbourg, the vitamins by Bezssonoff of Strasbourg, relationship of pathology to ophthalmology by Terrien of Paris, internal secretions by Francescetti and Gorin of Geneva, general ophthalmic semeiology by Terrien of Paris, diseases of the superciliary area by Villard of Montpellier, diseases of the lids by Aubaret of Marseilles, tumors of the lids and lacrimal caruncle by Kalt of Paris, and disturbances of the motor apparatus of the lids by Jean-Sédan of Marseilles. With the great variety of material, this volume is even more spotty in character than are its predecessors. The chapters dealing with examination of the eyes by various methods are probably the weakest that have appeared thus far. In contrast to that the chapter on tumors of the lids by Marcel Kalt is as complete and thorough as can be found anywhere in the literature. This volume contains fewer illustrations than the others, although the few color plates in the closing chapters are good. The general format of the volume complies with that set up for the entire series.

Food Control: Its Public Health Aspects. A Manual for Regulatory Officers, Food Technologists, and Students of the Food Industry. By James Houston Shrader, Ph.D., Instructor in Biochemistry, School of Hygiene and Public Health, Johns Hopkins University, Baltimore. Cloth. Price, \$4. Pp. 513. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1939.

This is a unique contribution to the literature on food control. It provides not only a discussion of the public health aspects of control measures but also a discussion of the nutritional significance of different phases of food technology. Each class of products is discussed from the points of view of technology, relation to public health and problems of regulatory control. The author, who is now editor of the *Journal of Milk Technology*, has had extensive experience in the subject matter covered by the book. The manual contains information about many new products that have been but recently placed on the market. It is a readable book that will be indispensable for all regulatory officers, food technologists and students of the food industry.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Corporate Practice Authorized Neither by Charter of Corporation nor by Dental Act.—The state of Indiana, on the relation of the board of medical examiners, sought to enjoin the Boston System Dentists, a corporation, from practicing dentistry in Indiana. The trial court denied the injunction and the state appealed to the Supreme Court of Indiana.

The defendant corporation was incorporated under the general laws of Indiana on March 2, 1917, "for the purpose of engaging in and carrying on the business of dentistry and every branch thereof; the manufacturing, buying, selling and dealing in dental supplies, artificial dentists' crowns and bridgework, porcelain and gold inlays and other merchandise; printing and advertising and doing all other acts connected with or incident to the business of dentistry or any branch thereof." The corporation maintained in the city of Gary an office with the usual facilities used by practicing dentists. It owned the equipment and paid the operating expenses of the office. Two licensed dentists used the facilities and carried on a dental practice in the office, fees being collected by a cashier employed by the corporation and remitted by her to its treasurer in Chicago. The dentists received, by way of remuneration, salaries fixed by contract and commissions depending on the volume of income.

The original dental practice act of Indiana, enacted in 1913, prohibited "any person" from practicing dentistry without a license, and this prohibition was still in effect at the time of the trial of this case. An amendment to the dental practice act became effective on March 9, 1917, seven days after the defendant's incorporation, providing as follows:

That it shall not be unlawful for any one duly licensed to do so, to practice dentistry, or to hold himself out as a practitioner of dentistry, under the name of any legally incorporated dental company, existing and in operation prior to the taking effect of this act.

It was conceded that the defendant had no license to practice dentistry. The substantial question before the court was whether the defendant was engaged in the practice of dentistry and what rights, if any, it possessed under its charter and under the dental practice act as amended in 1917. The corporation contended that (1) it was not engaged in the practice of dentistry; (2) the business in which it was engaged was specifically authorized by its charter and by the 1917 amendment to the dental practice act; (3) the injunctive process was not an appropriate enforcement remedy, and (4) to grant the injunction would constitute a forfeiture of its character and would destroy its vested rights in violation of the principles of constitutional law.

In the opinion of the Supreme Court, the defendant's method of doing business constituted the practice of dentistry on its part. It occupied the relation of master toward the licensed dentists who performed the actual services; they were its servants for hire. The regulation of the dental profession, the court pointed out, is not generally dissimilar in effect to that imposed on the practice of medicine, and it has been held that a corporation may not lawfully engage in the practice of medicine directly or by employing licensed persons for that purpose. *Herman v. Baker* (Ind.), 15 N. E. (2d) 365. The same rule is applicable to the practice of dentistry. The 1917 amendment to the dental practice act authorized any one licensed to practice dentistry to hold himself out as a practitioner under the name of any legally incorporated dental company existing and in operation prior to the taking effect of the amendatory act. This proviso, the court pointed out, was clearly for the benefit of persons legally licensed to practice dentistry. It may not be construed to extend any privileges to a corporation.

In answer to the contention interposed by the corporation that the remedy of injunction was not proper because the practice of dentistry without a license is a misdemeanor, punishable by fine and imprisonment, the court pointed to the fact that the dental practice act specifically authorizes the use of the injunctive process. But, the court continued, if an injunction is not specifically authorized the situation presented in the present

case would bring it within the rule applicable where the protection of the public welfare is involved. In such cases equity will intervene notwithstanding the fact that the wrong complained of may also be a crime.

To prohibit the corporation from engaging in the unauthorized practice of dentistry by injunction does not destroy any of its vested rights, the court said. The practice of dentistry is a personal privilege and not a matter of right. It is a profession and not a business. The corporation acquired no right to engage in that profession by reason of its articles of incorporation, adopted in 1917, because the state had already restricted the right to practice dentistry, by the dental practice act of 1913, in such a manner as to exclude corporations. Nor would the corporation's corporate franchise be forfeited by restraining it from unlawfully engaging in the practice of dentistry. By the terms of its charter, the corporation may legitimately manufacture, buy, sell and deal in dental supplies and other merchandise. It cannot be enjoined from engaging in that business; but it may not follow a skilled profession the practitioners of which are required to have a personal license.

The judgment of the trial court was therefore reversed with directions to enter judgment for the state permanently enjoining the corporation from engaging in the practice of dentistry in Indiana.—*State ex rel. Indiana State Board of Dental Examiners v. Boston System Dentists (Ind.)*, 19 N. E. (2d) 949.

Society Proceedings

COMING MEETINGS

- Academy of Physical Medicine, Richmond, Va., Apr. 24-26. Dr. Herman A. Osgood, 144 Commonwealth Ave., Boston, Secretary.
- Alabama, Medical Association of the State of, Birmingham, Apr. 16-18. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.
- American Association for the Study of Gout, Rochester, Minn., Apr. 15-17. Dr. W. Blair Mosser, 133 Biddle St., Kane, Pa., Secretary.
- American Association for the Study of Neoplastic Diseases, Louisville, Ky., Apr. 11-13. Dr. Eugene R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Anatomists, Louisville, Ky., Mar. 20-22. Dr. E. R. Clark, Dept. of Anatomy, Univ. of Pennsylvania School of Medicine, Philadelphia, Secretary.
- American Association of Pathologists and Bacteriologists, Pittsburgh, Mar. 21-22. Dr. Howard T. Karsner, 2085 Adelbert Rd., Cleveland, Secretary.
- American Association of the History of Medicine, Atlantic City, N. J., May 4-5. Dr. Henry E. Sigerist, 1900 East Monument St., Baltimore, Secretary.
- American College of Physicians, Cleveland, Apr. 1-5. Mr. E. R. Loveland, 4200 Pine St., Philadelphia, Executive Secretary.
- American Orthopedic Association, Kansas City, Mo., May 4-10. Dr. Ralph K. Gormley, 110 Second Ave. S.W., Rochester, Minn., Secretary.
- American Pediatric Society, Skytop, Pa., May 2-4. Dr. Hugh McCulloch, 325 North Euclid Ave., St. Louis, Secretary.
- American Society of Biological Chemists, New Orleans, Apr. 13-17. Dr. C. G. King, Dept. of Chemistry, Univ. of Pittsburgh, Pittsburgh, Secretary.
- American Surgical Association, St. Louis, May 1-3. Dr. Charles G. Mixer, 319 Longwood Ave., Boston, Secretary.
- Arizona State Medical Association, Tucson, Apr. 18-20. Dr. Leslie R. Kober, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Fort Smith, Apr. 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.
- Association of American Physicians, Atlantic City, N. J., May 7-8. Dr. Hugh J. Morgan, Vanderbilt University Hospital, Nashville, Tenn., Secretary.
- California Medical Association, Coronado, May 6-9. Dr. George H. Kress, 450 Sutter St., San Francisco, Secretary.
- Florida Medical Association, 29-May 1. Dr. Shaler Richardson, 111 West 29th St., New York, Secretary.
- Georgia, Medical Association of, Savannah, Apr. 23-26. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.
- Iowa State Medical Society, Des Moines, May 1-3. Dr. R. L. Parker, 3510 Sixth Ave., Des Moines, Secretary.
- Louisiana State Medical Society, New Orleans, Apr. 22-24. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, Apr. 23-24. Dr. Richard T. Shackelford, 1211 Cathedral St., Baltimore, Secretary.
- Minnesota State Medical Association, Rochester, Apr. 22-24. Dr. B. B. Souster, 493 Lowry Medical Arts Building, St. Paul, Secretary.
- Missouri State Medical Association, Joplin, Apr. 30-May 1. Mr. E. H. Bartelsmeyer, 634 North Grand Blvd., St. Louis, Executive Secretary.
- Nebraska State Medical Association, Omaha, Apr. 22-25. Dr. R. B. Adams, 416 Federal St., Lincoln, Secretary.
- New York, Medical Association of, New York, May 6-9. Dr. Peter Irving, 200 W. 42nd St., New York, Secretary.
- North Dakota State Medical Association, Minot, May 6-8. Dr. Albert W. Skelsey, 20 1/2 North Broadway, Fargo, Secretary.
- Northern Tri-State Medical Association, Battle Creek, Mich., Apr. 9. Dr. Benjamin Gillette, 320 Michigan St., Toledo, Ohio, Secretary.
- Pacific Coast Surgical Association, Portland, Ore., Apr. 3-6. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.
- Society for the Study of Asthma and Allied Conditions, Atlantic City, N. J., May 4. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Tennessee State Medical Association, Chattanooga, Apr. 9-11. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

37: 493-672 (Dec.) 1939

- Gliomas in Animals: Report of Two Astrocytomas in Common Fowl. E. Jungherr and A. Wolf, New York.—p. 493.
- Mammary Glands of Mature Female Mice of Strains Varying in Susceptibility to Spontaneous Tumor Development. W. U. Gardner, L. C. Strong and G. M. Smith, New Haven, Conn.—p. 510.
- Effect of Dihenzanthracene on Liver. A. Goerner and M. Margaret Goerner, Brooklyn.—p. 518.
- Dihenzanthracene Mouse Sarcomas: Histology. W. H. Lewis, Baltimore.—p. 521.
- Local Effect of Zinc on Development of Marsh Buffalo Adenocarcinoma. F. Bischoff and M. Louisa Long, Santa Barbara, Calif.—p. 531.
- Chromosomal and Extrachromosomal Influence in Relation to Incidence of Mammary Tumors in Mice. W. S. Murray and C. C. Little, New York.—p. 536.
- Artificial Benignancy of Neoplasm: III. Metabolism of Sarcoma 180 Growing at Different Rates. J. Muus, F. N. Craig and W. T. Salter, Boston.—p. 553.
- Retention of Immunizing Power by Shope Papilloma After Exposure to Ultraviolet Radiation. W. H. Woglom and J. Warren, New York.—p. 562.
- *Study of Fuchs Reaction for Cancer. O. Rosenthal, Philadelphia.—p. 566.
- Polarographic Studies of Human Blood Serums. A. C. Walker, Short Hills, N. J., and S. P. Reimann, Philadelphia.—p. 585.

Fuchs Reaction for Cancer.—Rosenthal reviews the literature on serologic tests for cancer. Of all the cancer tests based on reactions between serums and cancer-specific substances, only the test of Fuchs has been verified by many authors. Since technical difficulties, to which occasional failures of the reaction had been ascribed, were eliminated by Minibek, the author studied the value of the modified test and found that the Fuchs reaction demonstrates differences between serums from patients with and without cancer only in a statistical sense but is without real value for diagnosis in an individual case. The chief difficulty of the test lies neither in the technic of the reaction nor in the preparation of the substrates but in the fact that the selection of specific substrates of such activity that the reaction values are unquestionably beyond the range of error is a matter of chance. A comparison of the results of other authors using the Fuchs test supports these observations, although most of the conclusions are more favorable. Whether the test can be of any aid in the diagnosis and prognosis of cancer in the patient can be decided only if the mechanism of the reaction can be explained in detail.

American Journal of Clinical Pathology, Baltimore

10: 1-132 (Jan.) 1940

- *Observations on Human Beings with Cancer, Maintained at Reduced Temperatures of 75 to 90 F. L. W. Smith and T. Fay, Philadelphia.—p. 1.
- Current Conceptions of Physiology of Kidney. J. M. Hayman Jr., Cleveland.—p. 12.
- Renal Function. M. H. Barker, Chicago.—p. 21.
- Clinical Aspects of Renal Disease. L. Leiter, Chicago.—p. 30.
- Studies on Experimental Hypertension: XII. Experimental Production and Pathogenesis of Hypertension Due to Renal Ischemia. H. Goldblatt, Cleveland.—p. 40.
- A One Hour Renal Condition Test. W. G. Exton and A. R. Rose, Newark, N. J.—p. 73.
- Treatment of Pneumonia with 2-(P-Aminobenzenesulfamido) Pyridine. A. V. St. George, A. F. Kratzner and W. Magee, with assistance of W. S. Gibbs Jr. and L. Stix, New York.—p. 97.

Reduced Temperatures and Cancer.—From December 1938 to October 1939, Smith and Fay subjected thirty-three patients to seventy-five individual inductions of reduced body temperature ranging from 74 to 90 F. These patients were in the hopeless and terminal stages of cancer, presenting themselves chiefly for relief of pain. They have had all the surgical and radiation treatment indicated and have been as a whole in

extremely poor physical condition; emaciated, cachectic, often anemic. Physiologic data from a study of these patients while in this physical state, resembling "hibernation" in many respects, is recorded. An enormous amount of work will be necessary before any conclusions can be drawn. Previous to these studies it was the general impression that prolonged reduction of temperature below 94 or 95 F. was inevitably fatal. These studies have shown that patients can be maintained for from five to eight days at temperature levels in the eighties, that relief of pain can be regularly anticipated for from a few days to as long as five months, and that regressive changes in young embryonal cells, particularly in carcinoma, take place as a result. The authors believe that the lowered physiologic activity due to the low temperature interferes with the metabolism of these cells. The studies suggest that the entire body economy is reduced, that the circulatory rate and blood flow are slowed and that the liver is in a relatively dormant and inactive state as shown by low nitrogenous analyses of the blood. The basal metabolism is apparently reduced from 20 to 25 per cent. Lower figures may well be anticipated when special methods are devised for more accurate recording. The procedure is not entirely devoid of risk. It is perhaps more particularly applicable from the clinical standpoint to chronic cases for the control of pain, especially to the terminal stages of cancer of bedridden patients. Its usefulness in the therapeutic field otherwise remains a problem to be solved in the future.

- Pectinates, with Special Reference to Nickel Pectinate and Their Therapeutic Value. P. B. Myers and A. H. Ronse, New York.—p. 39.
- Gastrointestinal Pseudoleukemia: Report of Case. S. Tanuhausner and R. Davison, Tucson, Ariz.—p. 45.

"Clubbed Fingers" and Ulcerative Colitis.—Schlicke and Bagen point out that clubbing of the fingers is seldom a primary condition. Bronchiectasis, pulmonary tuberculosis, empyema and mediastinal or pulmonary tumor are commonly present. Isolated cases have been reported to follow various disorders of the kidneys and liver, amyloid disease and cachexia strumipriva. There has been little mention of clubbed fingers as a sequela of chronic ulcerative colitis. The authors review seven instances of clubbed fingers in patients under treatment for chronic ulcerative colitis seen within the last two years at the Mayo Clinic. In none of these cases was there evidence of any other primary disease. To explain clubbed fingers as a sequela of ulcerative colitis is as unsatisfactory as attempting to explain its more frequently associated occurrence with other conditions.

Vitamin B Complex and Digestive Disturbances.—Chesley and his associates state that a high percentage of forty-four patients with various functional digestive disturbances were improved by the administration of a vitamin B complex concentrate in large doses. That these patients were deficient in the vitamin B complex was suggested not only by the results of treatment but also by the demonstration of an abnormally low excretion of one of the vitamin B complex constituents (thiamin). Preliminary tests indicated that effectiveness of the whole complex is not due to vitamin B₁ (thiamin) or to vitamin B₂ (riboflavin). Part of the effectiveness is due to the action of the

nicotinic acid. The authors do not wish to suggest that nicotinic acid in pure crystalline form should find a place in the treatment of functional digestive disorders. The use of the whole vitamin B complex appeals to them as a more rational procedure because in their experience it produces better therapeutic results and it is probable that deficiencies of several vitamin B complex fractions are more common than deficiencies of a single factor.

Hemorrhagic Disease of Newborn Infants.—Quick and Grossman studied the prothrombin concentration of the blood of newborn infants with Quick's method. They conclude that at birth the prothrombin in the baby's blood is relatively high but often drops precipitously during the first days of life and then, strangely, is restored spontaneously. The frequency with which the prothrombin falls in normal infants makes it highly probable that all infants are in danger of hemorrhage during the first few days of life. In the recognized neonatal hemorrhagic disease it is likely that the fundamental cause is a delay in the spontaneous restoration of the prothrombin level. Consequently, if an infant should bleed accidentally the small loss of blood may be sufficient to reduce the already low prothrombin level to a point at which hemorrhage becomes difficult to control and a vicious circle is initiated. The cause of the prothrombin deficiency seems to be an inadequate storage of prothrombin or of vitamin K in the fetus. Presumably as soon as the baby is born the physiologic demands promptly exhaust the available prothrombin. As there is apparently a reserve neither of vitamin K nor of prothrombin, a marked decrease of the latter occurs. The condition is clearly due to a lack of vitamin K, for the prothrombin can be restored promptly to normal by giving the baby an oral concentrate of this vitamin and the serious fall in concentration can be prevented. Since the drop in prothrombin is distinctly a manifestation of vitamin K deficiency, the rise must be due to a supply of this vitamin which was not present at birth, and since the food intake during the first few days is scarcely sufficient to assure an adequate supply, another source must be sought. Bacteria readily synthesize vitamin K (Almquist). At birth the intestinal contents of the baby are sterile, but in a very short time, especially if the baby is allowed to suckle, bacteria are introduced and an intestinal flora is established. The time relation between the beginning of bacterial activity and the restoration of the prothrombin level makes it appear likely that the available vitamin K is of bacterial origin. The practice of putting the baby to the breast early may serve the primary purpose of introducing harmless but useful bacteria into the alimentary tract. Although no positive proof exists that neonatal cerebral hemorrhage is one form of "hemorrhagic disease," it seems very likely that it is and that the lowered prothrombin is the important factor. If the clotting agent were

normal in amount, the excess of thromboplastin which is present in the brain would speedily stop the hemorrhage. As the baby is apparently not born with a marked deficiency of prothrombin, its fall can be accomplished by administering vitamin K orally. But in the normal infant this hardly seems necessary. Perhaps a return to the practice of early breast feeding will be sufficient. But in any case of difficult labor with probable intracranial injury the oral administration of a concentrate of vitamin K should begin immediately and be continued for several days. Vitamin K should also be given promptly if slight oozing is noticed from the umbilical cord or any other small wound, or if blood appears in the stool or urine. Unless the hemorrhage is severe a direct blood transfusion need not be given, as vitamin K acts promptly. When the normal prothrombin level is once established in the baby it becomes difficult to cause any appreciable diminution. It is therefore usually possible to operate on a child after it is a week old without danger of untoward bleeding. But, if an operation must be performed earlier, the prothrombin should be determined by Quick's method and if it is low vitamin K should be given preoperatively.

Double Quotidian Temperature Curve of Gonococcic Endocarditis.—Futcher discusses a particular form of temperature curve which seems relatively specific for gonococcic endocarditis. The temperature charts of twenty-four patients with gonococcic endocarditis were examined. The diagnosis was established by postmortem examination in twenty-two. Of the two instances not studied post mortem one blood culture was positive for the gonococcus before death and the other patient, whose blood culture was also positive, recovered from her illness. All of these twenty-four patients were in the hospital for six days or longer. Eleven of the twenty-four temperature charts showed the double peaks of fever for a period of from five to twenty-two consecutive days, the average being ten days. The prototype of these eleven patients is one who, at 6 a. m., has a shaking chill lasting a few minutes followed by a rise in rectal temperature from an initial level of 98 F. at 4 a. m. to 105 F. at 8 a. m., with subsequent sweating and a precipitous fall to 98 F. at 4 p. m. Then a repetition of the chill and the rest of the episode follows at 6 p. m., and the temperature returns to 98 F. by 4 a. m. of the next day only to renew the twelve hour cycle. There was moderate variation in the timing of the episodes from day to day in the same patient. The double peak temperature curve was not present during the whole period that the patient was observed. Usually a patient with a previously intermittent curve lapsed temporarily into the twelve hour cycles for a period of from one to three weeks, the curve subsequently becoming irregular again. Four patients with gonococcic endocarditis who were being treated with sulfanilamide were having the double quotidian fever when the drug was first administered but the double peak disappeared within forty-eight hours and the temperature curve was lowered subsequently. The phenomenon therefore will probably not be observed among patients receiving sulfanilamide. The patients who never showed the cycles usually had a high and intermittent fever, often with a regular twenty-four hour cycle and diurnal variations from 5 to 7 degrees F. None of the charts of three patients with gonococcic septicemia uncomplicated by endocarditis sustained double peaks, although two of them showed an irregular, double quotidian curve for forty-eight hours. The explanation for the twelve hour febrile cycle in gonococcic endocarditis is not apparent to the authors, but they emphasize the phenomenon as a valuable aid to diagnosis, feeling that it deserves somewhat more prominence than is assigned to it.

Pneumococcic Pneumonia.—Dowling and Abernethy compared the value of sulfapyridine and serum in the treatment of pneumonia. From September 1938 through July 15, 1939, they treated 226 consecutive cases of pneumonia; ninety of the patients were given serum alone, 130 sulfapyridine alone and six extremely ill patients received both the drug and the serum. Typing of each patient's sputum was performed at least once. One or more blood cultures from and roentgenograms were taken of nearly every patient. Cultures were made of all exudates and from the lungs at postmortem. From August until Nov. 17, 1938, before sulfapyridine became available, patients were treated with serum alone. After that, patients with type I pneumonia were alternated, one being given serum and the next

the drug. When a serum for a particular type was on hand, it was used; otherwise the patient was treated with sulfapyridine. Among the seventy cases of type I, II, V, VII or VIII pneumonia treated with serum there were ten deaths (14.3 per cent). There were five deaths among the fifty-two patients treated with sulfapyridine (9.6 per cent). The four individuals treated with a combination of serum and sulfapyridine died. When only the bacteremic cases are considered, there were three deaths among seventeen patients treated with serum and the same number among sixteen patients treated with the drug. When treatment was begun during the first four days of the illness, the mortality rate for the forty-six patients receiving their first dose of serum during this early period was 10.8 per cent and for the thirty-four receiving sulfapyridine it was 2.9 per cent. When pneumonias caused by all types of pneumococci are considered, the mortality of the ninety-six treated with serum was 16.7 per cent as compared to 11 per cent of the 136 treated with sulfapyridine. Among the bacteremic cases the percentages were 23.8 and 20, respectively. The effect of the therapeutic agents on the course of pneumonia is also evaluated by the incidence of empyema. Among the ninety-six serum-treated cases there were six cases of empyema, while among the 136 treated with sulfapyridine empyema developed in four. In comparing the two therapeutic agents with regard to their ability to cause a rapid crisis, the authors find that the most definite results were obtained in the pneumonias caused by types I, II, V, VII and VIII pneumococci. Among the sixty patients in this group who recovered after serum treatment, a crisis occurred within twelve hours in 43.3 per cent, within eighteen hours in 58.3 per cent and within twenty-four hours in 61.7 per cent. The corresponding figures for those receiving sulfapyridine were 29.8, 46.8 and 63.8 per cent. In short, an early crisis occurred more frequently among those treated with serum, but after twenty-four hours crises occurred as frequently among the patients receiving sulfapyridine as among those given serum. When pneumonias caused by all types of pneumococci are considered, the same trends are evident but to a much less degree. While both serum and sulfapyridine are of great value in the treatment of pneumonia, the authors do not believe that conclusions may yet be drawn as to their relative value in its routine treatment.

Hypopituitarism, Chloride Excretion and Adrenocortical Function.—According to Stephens, six of seven patients with clinical hypopituitarism, when studied under standard conditions of salt depletion, showed increased concentrations of chloride in the urine similar to that which has been found to be characteristic of adrenocortical insufficiency. Symptoms suggesting those of Addisonian crisis developed in four of the six patients. These symptoms were promptly relieved by the intravenous administration of sodium chloride, dextrose and adrenal cortex extract. Symptoms did not develop in two patients and chloride excretion was favorably modified after the administration of sodium chloride and adrenal cortex extract. One patient experienced striking clinical improvement during the administration of sodium chloride and adrenal cortex extract. These observations are interpreted as confirmatory evidence of the occurrence of chronic adrenocortical insufficiency in clinical hypopituitarism, presumably secondary to withdrawal of the adrenotropic anterior pituitary principle.

Id.: III. Classification. P. M. Andrus, London, Ont.—p. 104.

Intrapleural Pneumonolysis.—Newton treated 146 consecutive patients requiring intrapleural pneumonolysis. The number of pneumonolyses performed was 182. Consideration of a patient for the operation depends on the presence of an incomplete pneumothorax of from one to six months in which collapse and rest of the diseased lung is prevented by pleural adhesions. In 128 cases, or 87.6 per cent, there was evidence of probable healing of the lung after pneumonolysis. The author believes that the electrosurgical technic is preferable and safer in experienced hands than the galvanocautery method. The scope of operable adhesions may be widened by its use and risk of complications diminished. Multiple stage intrapleural pneumonolysis is wiser in serious risk cases. The risk of serious operative and postoperative complications in cases in which adhesions are of such size and attachment as to make the risk of damage to lung or serious hemorrhage probable contraindicates intrapleural pneumonolysis.

Chronic Bronchiectasis.—Andrus describes four roentgenologic "cardinal signs" of bronchiectasis: generalized increase in density of the pulmonary markings, ring shadows, displacement of organs and chronic pneumonia. He believes that the presence of any one of these signs warrants a suspicion of bronchiectasis. When two of these "cardinal signs" are well established, such suspicion is greatly enhanced. The presence of three or more of these shadow changes warrants a diagnosis of bronchiectasis, ranging from probable to presumptive or positive, according to the development of the shadows and the clinical associations.

Parasitology: Round Table Discussion. E. C. Faust, New Orleans.—p. 1230.

Parenteral Sulfapyridine.—Finland and his associates prepared a dextrose-sulfapyridine solution for intravenous and subcutaneous injection. Eighteen patients were suffering from severe acute infections (pneumonia, meningitis, peritonitis, gonorrhea (?) arthritis) and the injections were given as a preliminary to oral sulfapyridine therapy. In two cases the injections were followed by specific serum therapy. The three patients who were not severely ill were the subjects of comparative studies on sulfapyridine and related compounds given by various routes. Sterile physiologic solution of sodium

chloride was used as the diluent. The amounts of the drug in each injection varied from 2.5 to 5 Gm. It was usually given slowly diluted to 1 per cent. The drug appeared within fifteen minutes in the urine. In the spinal fluids the concentration of the drug up to four hours after an injection was only one half or less than that of the blood. The drug appeared rapidly in the stomach contents and was found there in higher concentrations than in the blood. Reactions from the injections were usually of minor importance considering the severity of the cases treated. In one case convulsions during the injection were rapidly followed by collapse and death, and in a second the injections may have contributed to the early onset of pulmonary edema. None of the patients with typical pneumonia showed definite improvement before oral sulfapyridine therapy was begun. The observations suggested to the authors that the effects of the dextrose solution were not as striking as or equivalent to those from corresponding amounts of sulfapyridine or of its sodium salt orally.

Intravenous Calcium in Occlusive Vascular Disease.—Weichsel injected calcium salts intravenously in cases of occlusive vascular disease. Recordings of pulse amplitude before and after injection were made in thirty of these with the Tycoos recording oscillogram. In other cases, observations were made with the Pachon-Boulitte oscillogram. Both instruments showed an appreciable augmentation of the pulse amplitude in a considerable number of cases. The most striking phenomena, however, were relief from pain and increased ability on the part of the patients to walk. This needed explanation. The general flush and the feeling of warmth after the infusion of calcium salts lead one to believe that superficial vessels are being dilated. This impression is strengthened by the sensation of heat in an extremity that previously was cold for months or years because of deficient circulation. The author states that his observations tend to support the view that calcium stimulates the parasympathetic. The author has not seen either thrombosis or severe toxic response in thousands of injections, other than the flush or a slight nausea. Clinically, relief from pain lasts about twenty-four hours, later becoming semipermanent as treatment is continued. Night cramps and rest pain have been consistently relieved. Previously cold extremities become warm again. Patients generally return of their own volition for treatment after the first course is over. It is not uncommon for patients to remain relieved for as much as two years at a time. Calcium gluconate was used at first. The method now used is to add to an infusion of physiologic solution of sodium chloride the required amount of a 50 per cent stock sterile solution of calcium chloride. This is done after the injection is started with the physiologic solution of sodium chloride to be sure that the venipuncture is clean. A 300 cc. pyrex arsenamine tube is used, and glass Luer slip connectors show by reflux of blood when the vein has been entered. Because of the synergism of calcium and digitalis, no digitalized patient should be given calcium. Death may result. All patients received 2 Gm. of calcium chloride once a week for twelve weeks. Claudication distances were materially and consistently increased after treatment. Ulcers were healed with this treatment alone.

Cardiovascular Effects of Large Doses of Metrazol.—Messinger and Moros list changes in the physical signs, blood pressure and electrocardiograms of fourteen men receiving metrazol alone as well as metrazol during the course of insulin hypoglycemia. The metrazol injections as a rule induced a transitory mild to moderate acceleration of cardiac rate (from ten to thirty beats per minute) and at times transitory cardiac irregularities most often of the type of auricular extrasystoles, and sinus arrhythmia, with ventricular extrasystoles more rarely. No instance of auricular fibrillation, although this has been reported by another investigator (Hadorn), has been observed by the authors. Patients who are "sensitive" or "have been sensitized" (by previous treatment with insulin) may show temporary signs of aortic dilatation phenomena, analogous to the known effects of a mild hyperadrenalinemia. Except in such "sensitized" patients, who had electrocardiograms possibly indicating a slight tendency toward diminished coronary oxygenation, the electrocardiograms after convulsions invariably indicated either no change or improved coronary oxygenation, associated with the more vigorous heart action.

Interstitial Keratitis and Food Allergy.—The Deans and McCutchan encountered six persons with interstitial keratitis who presented a characteristic appearance and who were relieved by removing certain foods from their diet. In all six cases the ingestion of at least one food would reproduce clinical symptoms after its withdrawal from the diet resulted in relief of clinical symptoms. The disease commences with slight irritation, mild discomfort, lacrimation and redness. These symptoms continue for weeks, often with remissions, but generally become more and more severe. They fail to respond to local treatment. After the symptoms have continued for some weeks and the process has involved the central portion of the cornea, vision becomes slightly hazy. The slit lamp shows faint, irregular, gray or yellowish gray interstitial opacities in the cornea, at first localized in one quadrant. Loops of scleral vessels soon develop deep in the corneal stroma toward the lesions. As the disease progresses, the opacities increase in number and in density, extending to all portions of the cornea. Scar tissue invades the stromal layers. Lesions rarely break through the anterior epithelium of the cornea to produce ulceration. This condition is similar to that of "recurrent vascular keratitis of unknown origin" (Doggart, 1931). Specific treatment is the removal from the diet of all offending foods, which are ascertained by history, elimination or cutaneous test. When this is done the ciliary injection and pain disappear in forty-eight hours. Opacities which are not escharotic gradually lessen in depth; otherwise the process is arrested. The vessels in the corneal stroma continue to function for a long time, although their diameters seem to be lessened. If the sensitizing food is again ingested after the process is arrested, symptoms reappear within twenty-four hours. The disease was reproduced only twice, as no patient would submit to further experimentation.

Primary Glaucoma.—Schoenberg contends that the eyes of some patients with primary glaucoma register states of anxiety just as those of other persons with glaucoma record changes in weather, poor illumination, poorly balanced diets, cardiovascular disturbances, acute febrile diseases and sudden increases in blood pressure. States of anxiety cause a widespread and more or less intense disturbance of the physiologic processes throughout the entire body. The ocular disturbances occurring during acute states of emotion are increase in the size of the pupils, enlargement of the interpupillary fissure, bulging of the eyes, hypersecretion of the lacrimal glands and spasm of the retinal arteries (in older patients). Most of these manifestations are similar to those appearing after a sudden and large increase of epinephrine in the blood stream. It is well known that under conditions of emotional stress there is a marked increase of epinephrine-like substances in the blood and tissues. The autonomic nervous system and the endocrine glands reach every organ and tissue in the body. Evidence shows that the two parts of the autonomic nervous system

(the sympathetic and parasympathetic) are out of balance within the glaucomatous eyes and that states of anxiety have a different effect on glaucomatous eyes than on normal eyes. The following are some evidences for the first statement: 1. The power of accommodation is diminished and there is a tendency for the pupils to be somewhat dilated (underaction of the parasympathetic system). 2. Epinephrine hydrochloride dilates the pupil of a glaucomatous eye when instilled in the fornix but it does not do so in a normal eye. 3. The pupils of glaucomatous eyes usually need a stronger solution of pilocarpine for contraction (showing that the parasympathetic innervation of the sphincter pupillae is hypotonic). 4. Atropine in the usual doses increases appreciably the intra-ocular pressure of the glaucomatous eye and not of the normal eye. 5. Pilocarpine and physostigmine salicylate reduce the ocular tension in certain glaucomatous eyes, while the tension in normal eyes remains unaffected. 6. Drugs with a specific action on the autonomic nervous system also have a specific action on glaucomatous eyes. 7. Emotional upsets, febrile diseases and sleeplessness have a strong unbalancing influence on the function of the autonomic nervous system and also tend to increase the ocular tension. Proving the effect of states of anxiety on glaucomatous eyes, the following facts are cited: 1. The author's patients presented such evidence. 2. The ophthalmologic literature contains reports (vague and meager, though they are) of attacks of acute glaucoma following violent emotions. 3. In some cases of glaucoma a recrudescence of the condition is attributable to states of anxiety. 4. Many patients, when permitted and encouraged to talk, have described minor or major attacks of glaucomatous crises during or following states of anxiety. 5. There is no case on record of an attack of glaucoma in a normal eye following an emotional upset.

Vitamin B and Nerve Deafness.—The possible relation between deficiency of vitamin B and at least some forms of nerve deafness, pointed out by Selfridge, prompted Veasey to review the literature (up to 1938) on vitamin B, from which he finds that a vitamin B deficient person may have symptoms referable to the nervous, vascular or gastrointestinal system, the endocrine glands or the organs of special sense. The author cites seven cases of impaired hearing for the treatment of which he used vitamin B. The results suggest that there is a possibility of helping some persons by this means but that at the present time there are no means of selecting the patients who may be improved.

Argyria from Intranasal Medication.—Bryant cautions that argyria can result from the use of silver-containing intranasal medication. A 100 per cent increase in such cases reported occurred during a recent period of five years. Walsh and Cannon observed that all their rabbits treated intranasally with 5 per cent mild protein silver and neosilvol showed changes in the lungs, consisting of edema, necrosis, desquamation of septal cells and bronchopneumonic lesions. These changes were more marked when the animal had the snuffles. When to these observations is added the real danger of the production of argyrosis, it seems that a clear case against the intranasal use of silver preparations has been established. Measures should be taken to warn the public of the danger of the production of argyria by long-continued self medication with silver preparations.

Microscopic Changes After Sulfapyridine.—Antopol and Robinson observed concretions in certain animals after the administration of a large single dose of sulfapyridine, but the results were more striking after repeated doses on successive days. From their studies the authors cannot conclude whether the precipitation of the acetylated sulfapyridine in the urine is always primary or whether it is dependent on initial degenerative changes in the renal parenchyma or on a combination of the two. With the oral administration of sodium sulfapyridine, smaller doses were necessary for urolith formation in the rat, rabbit and monkey. Histologically the degenerative changes in the kidney were more pronounced than those from sulfapyridine. When the drug was administered rectally, a hemorrhagic reaction with some necrosis of the mucosa was frequently encountered.

Picrotoxin for Acute Barbiturate Poisoning.—Eisele and Brosin report two cases of barbiturate poisoning treated with picrotoxin. Although the amounts of barbiturate ingested were not massive, the lapse of time between the ingestion of the barbiturate and its discovery was ample for complete absorption of the drug to take place. The symptoms (deep coma, absence of reflexes, flaccidity of musculature and cyanosis) pointed to a serious poisoning in both cases. In both cases, picrotoxin repeatedly produced definite awakening phenomena which subsided on withdrawal of the drug; therefore it, with other supportive measures, was continued until recovery ensued. A complete abortion of a three months pregnancy occurred in the first case shortly after the onset of picrotoxin therapy. It is debatable whether the abortion resulted from the treatment or from the barbiturate poisoning itself. However, the experimental work of Kunisho suggests that the picrotoxin may have been the cause of the abortion; Kunisho found that small doses of picrotoxin always stimulated the uterus of the rabbit. Bronchopneumonia is a frequent complication of barbiturate poisoning. Picrotoxin, by shortening the period of coma, should eliminate or mitigate this complication in many instances.

Treatment of Severe Bronchial Asthma.—Keeney believes that the treatment of patients with severe bronchial asthma is simplified by classifying the disease into three groups: severe acute bronchial asthma, intractable asthma (status asthmaticus) and severe chronic bronchial asthma. Patients with severe acute asthma should first receive from 0.3 to 0.5 cc. of epinephrine hydrochloride (1:1,000). Such a dose should be repeated every fifteen minutes until four doses have been administered or until relief is apparent. To prevent

recurrence of asthma, an intramuscular injection of from 0.75 to 1 cc. of epinephrine-in-oil should follow. One of the barbituric acid derivatives may be given as a sedative. An injection of from 0.3 to 0.5 cc. of Schlesinger's solution (0.000125 Gm. of scopolamine hydrochloride, 0.01 Gm. of morphine hydrochloride and 0.015 Gm. of ethylmorphine hydrochloride) is permissible if the patient is badly in need of rest. Epinephrine therapy is best for hypertensive patients with severe asthma. Patients with intractable asthma fail to obtain relief from the usual epinephrine preparations. They are not "epinephrine fast." The intravenous injection of 100 cc. of a 50 per cent solution of sucrose to which has been added 0.5 cc. of epinephrine hydrochloride (1:1,000) or the injection of 0.48 Gm. of aminophylline diluted in 10 cc. of physiologic solution of sodium chloride may give temporary relief. The continuous or intermittent inhalation of an atmosphere of 100 per cent oxygen or of 80 per cent helium and 20 per cent oxygen is a physiologically sound therapeutic measure. To improve the cardiac action, digitalization should be carried out in from twenty-four to forty-eight hours and then a maintenance dose should be provided until the patient is free from asthmatic symptoms. From 60 to 120 cc. of a mixture of equal parts of ether and olive oil may be instilled rectally to induce sleep. Patients with severe chronic bronchial asthma require frequent daily and nocturnal injections of epinephrine hydrochloride (1:1,000). Epinephrine-in-oil intramuscularly requires fewer injections and is followed by longer symptom-free periods. The value of intratracheal injections of iodized oils is generally overrated.

Tetanus and Lesions of Spine in Childhood.—Dietrich and his colleagues state that during the last eighteen years at the Children's Hospital the mortality from tetanus has dropped from 80 to 8 per cent. Of the surviving patients who have been examined, 69 per cent showed lesions in the thoracic spine. During the years 1921 to 1933 the plan of treatment was débridement and the injection of large amounts (from 15,000 to 100,000 units) of tetanus antitoxin locally, intramuscularly, intravenously and intrathecally. Of the fifteen patients in this group twelve died, eleven deaths occurring within fourteen hours of the institution of treatment. In every instance the disease picture was changed from one of tetanus, with relatively low temperature and pulse rate and clear sensorium, to a condition resembling grave bulbar involvement. The three patients who recovered showed similar but less serious reactions. After short periods of grave uncertainty the reaction subsided suddenly but the tetanus improved more slowly. One of these patients had such severe reactions following each intraspinal injection of antitoxin that the outcome after each injection was questionable. Post-

mortem studies of four of the patients who died suddenly showed marked medullary and cerebral edema and mild to moderate inflammatory changes. Thus it appears that the hypersensitive central nervous system of the patient with tetanus cannot withstand the added insult of a sterile meningitis or increasing intracranial pressure. Only one of the thirteen patients treated from 1933 to the present time died. This death occurred three hours after the first administration of 20,000 units of antitoxin intravenously. Eight of these twelve patients were not given intrathecal injections of serum. The remaining four had severe reactions after the administration of serum intraspinally, but somehow they survived a few critical hours. The temperature and pulse rate then fell rapidly, although tetanic activity continued. The authors feel that these dramatic elevations and subsequent rapid falls of temperature and pulse rate were entirely dissociated from the course of the tetanus. The reactions always occurred after treatment and subsided long before the tendency to severe tetanic convulsions had disappeared. Two of the surviving patients who were given intravenous but no intrathecal injection of serum showed similar severe reactions, so it is impossible to ascribe all of these "bulbar crises" to sterile meningitis. In one of the latter cases, when death seemed imminent, hypertonic sucrose solution was given intravenously in the belief that the reaction was due to cerebral edema. A dramatic improvement followed within a few hours. Four of the surviving patients who received only local and intramuscular injections of serum were, with one exception, the only patients who did not have a frightening reaction following treatment. Every patient in this group received large doses of sedatives: amytal, avertin with amylene hydrate and, more recently, seconal (a barbitol preparation). The authors conclude that between 1921 and 1933 something was done that precipitated critical reactions and death. In every instance reactions followed either intrathecal or intravenous administration of antitoxin. Therefore it seems that the intrathecal administration of tetanus antitoxin for juvenile tetanus should be discontinued because of the severe reactions (sterile meningitis, cerebral edema and death) which follow its use. It is a frequent cause of death of children so treated. With the increasing recovery rate there has been a marked increase of vertebral deformities. The possibility of preventing some of these by early and vigorous sedation suggests itself. By the time anything can be done for the patient with a vertebral deformity, repair has occurred and the deformity remains. As the condition is practically symptomless, treatment has been found useless.

Clay Shoveler's Fracture.—Hall reports thirteen cases of occupational injury which he terms "clay shoveler's fracture." The history of the accident is the same in practically all cases. The laborer (digging drains in clay soil) throws up a shovelful of clay usually from 10 to 15 feet, the clay sticks to the shovel and the worker feels a sudden stab of pain and sometimes hears a crack somewhere between the shoulders and is unable to continue working. It is suggested that the causation of clay shoveler's fracture is closely associated with the origins and actions of the trapezius (middle portion), the rhomboideus major and the rhomboideus minor; the serratus posterior superior acts merely as an accessory to these muscles, for when the worker is in the act of throwing this muscle is probably in full contraction, thus helping to fix the chest. The three possible mechanisms of this fracture are direct muscle violence, reflex muscle contraction and whiplike pull transmitted through the supraspinal ligaments. Early removal of the detached fragments is doubtless the treatment of choice.

Influence of Nitrogen Content of Diet on Calory Balances.—Hawks and her associates observed five preschool children serving as subjects for two long-time balance experiments. In each experiment they received two diets, the first of which contained daily 3 Gm. and the second 4 Gm. of protein per kilogram of body weight. The increase in the protein content of the diets did not change the constant level of calory utilization. The children in each experiment reacted in the same manner, although there were slight differences in the results of the two experiments. The period to period variations for excretory values remained constant on the two diets and the absorption and retention figures varied in the same manner and to the same degree as the intake values. The change from the diet containing 3 Gm. to the one containing 4 Gm. of protein affected the calory balance as follows: 1. It increased the nitrogen content of the excreta, thus increasing the actual number of calories eliminated. 2. It increased the average proportion of the intake calories eliminated from 7.3 to 12 per cent. Thus, subtracting 10 per cent from the intake values to care for excretory losses does not always give accurate results. 3. It reduced the actual number, as well as the percentage, of the intake calories available for body needs, but at the same time it produced greater weight gains in the children.

Silent Nephroma.—Ostrum and Fetter use the term silent nephroma for a group of far advanced malignant renal neoplasms with extensive metastases which, because of the site of metastases and the absence of urinary signs and symptoms, lead clinicians to suspect structures other than the kidneys as the possible source of disease. They encountered twenty-one such cases in eight years. In all the cases the chief complaints were referred not to the primary source of disease but to extensive metastases of other parts. Hematuria was observed in only three cases. Other complaints so overshadowed the bloody urine that the possible diagnosis of renal tumor was overlooked. Two of the patients presented themselves for medical attention because of painful knee joints. Examination of the chest of one of these patients revealed the presence of pleural effusion for which no explanation could be given and x-ray examination of the knee showed little involvement.

Repeated tapping of the chest was done and the knee was treated by physical therapeutic measures with some improvement. The patient returned at a later date with much increase in the pain and swelling of the knee and increased dyspnea. Repeated examination of the knee revealed an extensive osteolytic malignant lesion of the lower end of the femur. Necropsy showed a large hypernephroma of the right kidney with extensive metastases to the regional nodes, lungs, pleura and lower end of the right femur. Ten patients presented themselves with complaints of abdominal pain of various types and locations. Ten patients complained of various respiratory symptoms either as their cause of distress or in association with other more urgent symptoms. In seven instances the clinical history and physical signs were so suggestive that a diagnosis of advanced pulmonary tuberculosis was made. The authors state that the clinical triad of hematuria, pain and abdominal tumor is by no means essential to suggest disease of the urinary tract. If any one of these three manifestations is observed, a uroentgenographic study is indicated, provided a definite diagnosis is not otherwise made. The occurrence of even a single instance of gross or microscopic hematuria should always be viewed with serious concern. When uroentgenographic studies are performed, a conclusive opinion should not be formulated on the basis of a single examination. In such cases studies should be repeated at intervals.

Treatment of Acute Gonorrheal Urethritis.—To evaluate four different methods of treating acute anterior gonorrheal urethritis, Morse and Hirsch treated twenty-five cases by each method: sulfanilamide, sulfanilamide and anterior injections of silver protein, anterior irrigations with silver protein preceded by potassium permanganate irrigations, and daily anterior irrigations with a suspension of colloidal silver. All the patients were seen within five days from the onset of discharge before having any previous treatment and only initial infections were selected. The dosage of sulfanilamide of the first group of patients was 80 Gm. For the first two days 5.33 Gm. was given each day in four divided doses, 4 Gm. for the following two days and then 2.66 Gm. until the entire amount had been taken. The average duration of the disease in these cases was 39.1 days with extremes of from nine to ninety-three days. From the standpoint of complications, 56 per cent had none. Arthritis or epididymitis did not develop in any patient. Prostatitis developed in 8 per cent and the infection extended into the posterior urethra in 36 per cent. The average duration of the disease in the second group was fifty-one days. The extremes were sixteen and ninety-three days. There were no complications in 32 per cent of the cases, the infection in 52 per cent extended to the posterior urethra, epididymitis developed in 12 per cent and prostatitis developed in 4 per cent. The average duration of the disease of the third group of patients was fifty-one days with extremes of from thirty-eight to eighty-two days. The incidence of complications in this group was significantly higher. In only 30 per cent of the

cases was the infection kept localized to the anterior urethra. In 20 per cent the only complication was a posterior urethritis, but in 50 per cent epididymitis or prostatitis developed. The average duration of the disease of the remaining twenty-five patients treated by daily anterior irrigations of a suspension of colloidal silver was 46.9 days, with extremes of eighteen and ninety-six days. Of these cases 64 per cent remained uncomplicated for the duration of the disease, in 24 per cent the disease extended into the posterior urethra and in 4 per cent prostatitis, epididymitis or arthritis developed. The authors' conclusions are that sulfanilamide without supplementary silver irrigations gave the most satisfactory results and that a colloidal suspension of metallic silver is preferable to protein silver preparations in cases in which the use of silver is desirable.

Cardio-Omentopexy in Angina Pectoris.—Strieder and his associates review the literature on the revascularization of the ischemic heart. Beck was the first to make an attempt at revascularization of the ischemic heart in the human subject. Using the pectoralis major muscle as a pedicled graft, Beck attempted to bring a new blood supply to the heart in a human subject. O'Shaughnessy, who also experimented on cardiac grafting, used instead of muscle a pedicled omental graft. O'Shaughnessy has thought that the control of postoperative shock is an easier matter following cardio-omentopexy than following Beck's operation. Moreover, cardio-omentopexy is less time consuming and, other factors being equal, the omentum is obviously a better vascularizing agent than is the pectoralis major muscle. Because of these considerations the authors have concluded that cardio-omentopexy, when feasible, is the operation of choice for the establishment of a new blood supply to the heart by surgical means. They have performed it in two cases. In the selection of cases for operation they insist on the fulfillment of several requirements. There must be indisputable evidence of coronary heart disease with angina pectoris. At present the authors insist also that the patient be under 60 years of age and not obese. Serious complications in other organs are contraindications. Patients with marked hypertension and cardiac enlargement are rejected. Furthermore, the authors are of the opinion that patients who give evidence of congestive failure are not suitable candidates for operation. They describe the technic of cardio-omentopexy and review the postoperative course. They stress that the technic of this operation must be seriously concerned with the prevention of postoperative diaphragmatic hernia, as well as with the attachment of omentum to the heart. They report two cases in which they resorted to cardio-omentopexy. They think that many more patients must be operated on before any sweeping conclusions can be drawn, but they believe that the principle of revascularization is sound.

Infantile Paralysis Spread by Sewage-Polluted Waters.—Ellsworth says that in 1935 Massachusetts was visited by an epidemic of infantile paralysis. Fall River, with 114 cases reported, had the highest incidence of any city or town. Having but recently observed the effect of sewage on the bathing beaches at Fall River, the author wondered whether this pollution had any effect on the high incidence of infantile paralysis in that city. It is his conviction that there is sufficient presumptive evidence to warrant further investigation and research. He formulates the argument as follows: Since epidemic infantile paralysis occurs almost invariably during the summer, it is reasonable to assume that the disease may be spread not only by direct or indirect personal contact but also by some agency which is effective during the warm summer months. From the evidence in Massachusetts, the incidence of the disease during

epidemics is generally highest in communities situated along the seacoast or along rivers the waters of which are subject to sewage pollution. It has been possible to produce the disease in monkeys from the virus obtained from human stools of a case of abortive poliomyelitis as long as twenty-five days after the onset of the disease. It has also been shown that the virus in refrigerated human stools remains viable for at least ten weeks. For every recognized case there are apparently many unrecognized cases by which infection can be spread. During epidemics, and probably at other times, the virus from active cases or from carriers is undoubtedly present in the sewage of an affected community. Infection by way of the olfactory nerves is possible, and it appears probable that this is a common way of contracting the disease. Given a sufficient concentration of the virus in sewage-polluted water, it is conceivable that infection can be caused by the admission of such water into the nasal passages of a bather. While the possibility of infection by bathing in sewage-polluted water has been considered in the past and tentatively dismissed for lack of evidence, sufficient additional knowledge has been accumulated in recent years concerning infantile paralysis to warrant reconsideration of the conclusions reached by previous investigators. In any future epidemic it would seem advisable that more attention be given to this possibility. The author realizes that this theory of transmission of infection has weaknesses. Until the reason for this seasonal occurrence has been discovered, any rational theory of transmission that has not been definitely disproved deserves consideration.

Ludwig's Angina.—Williams points out that the mortality in thirty-one recent cases that he collected from five local hospitals was 54 per cent. Such a rate suggests that the disease does not receive proper recognition and treatment. In Ludwig's angina a massive swelling, often bilateral, always brawny and tender but rarely fluctuant, involves the suprahyoid region, being extreme in the submaxillary area. The overlying skin is conspicuously free of inflammation, showing only edema. The floor of the mouth is raised, edematous and brawny. The mucous membrane beneath the tongue is often ulcerated and dirty grayish white. The tongue is swollen and pushed upward, and it may become so crowded by sublingual edema that its tip protrudes between the teeth. Respiratory obstruction, due to blockage of the airways by an elevated or edematous tongue, is frequent. Emergency tracheotomy was performed on eight of thirty-one patients in this study. Four patients on whom tracheotomy was not done died of asphyxia. Bronchopneumonia complicated eight cases, seven of which terminated fatally. Extension of the infection took place in eight cases, seven of which were fatal. The

aims of treatment are to establish an airway, to relieve tension, to secure drainage and to combat the infection through supplementary measures. Tracheotomy is the most dependable means of securing an adequate airway. The tracheotomy incision should commence just below and slightly anterior to the angle of the jaw and run forward, parallel to and about 1 cm. below the body of the mandible, until it reaches the midline anteriorly. It should divide the deep cervical fascia, the mylohyoid diaphragm and the anterior belly of the digastric muscle penetrating upward so that the tongue and the mucous membrane of the floor of the mouth may be explored. Such an incision lessens tension and improves the airway. The choice of anesthesia warrants deliberation. At the Boston City Hospital pentothal was used in four and evipal in two cases of Ludwig's angina of the present series. Pentothal sodium is offered as a suggestion which future experience may or may not substantiate. Its use must be restricted to those familiar with the administration of pentothal. Sulfanilamide is of great value in cases showing positive *Streptococcus haemolyticus* cultures. Zinc peroxide is indicated when anaerobic organisms are present.

Malignant Disease of Face and Oral Cavity.—New and Hertz review the histories of the 233 patients up to 30 years of age who were treated for malignant disease of the face, mouth, pharynx or larynx. The number of cases of malignant disease increased with each succeeding decade. There were 100 cases of squamous cell epithelioma, and the five year survival figures were similar to those of other observers. In other words there is real prognostic value in grading such malignant growths, as one can offer the patients with grade 1 lesions a 90 per cent chance for recovery whereas the prognosis for those with grade 4 lesions is very poor (3.8 per cent). Malignant disease of the tongue, palate, tonsil, pharynx, upper jaw and antrum, lower jaw and larynx in young persons is thought to carry a poor prognosis. However, of the seventy-three patients who were traced, twenty-four (32.9 per cent) were living five years after treatment and of the thirty-six patients who were traced eleven (30.6 per cent) were living ten years after treatment. If cancer of the lip is included, of the 111 patients who were traced fifty-six (54.4 per cent) were living five years after treatment and of sixty-three traced for ten years thirty-two (50.7 per cent) were living.

Acute Appendicitis.—Busch and Spivack base their remarks on an analysis of 635 consecutive cases of acute appendicitis at the Beth Israel Hospital in which about seventy different surgeons, including twenty house surgeons, performed operations. The mortality was 2.2 per cent. The factors found to contribute to the mortality have been the duration of the disease and the use of cathartics. Diabetes was also found to be a serious complication. Cathartics definitely increase the severity of the disease. There should be no temporizing in cases suspected of being acute appendicitis when diabetes is a complicating factor because the pathologic process advances with great rapidity in such cases. Gangrenous appendicitis with perforation gave the highest mortality in the series. The general rule in this hospital is to operate immediately when the diagnosis of acute appendicitis has been established.

Prognosis in Celiac Disease.—Hardwick followed up seventy-three cases of celiac disease observed between 1923 and 1938. The diagnosis of celiac disease was made on the history of diarrhea, anorexia and loss of weight, accompanied by the classic clinical features and the finding of an excess of normally split fat in the stools on more than one occasion. Fifteen years has elapsed since the first patient was seen and the oldest living subject is now 16½ years old. Twenty-two of the patients died in the hospital, and all but ten (14 per cent) of the remainder have been traced. Four other patients died when the disease was not active. Those alive have been examined to determine if the disease was active, cured or quiescent, or if it had left any trace of its activity. Death was usually due to an exacerbation of the disease, the diarrhea increasing and dehydration and intoxication becoming marked. Only four children died from bronchopneumonia. Seventeen patients appeared to have recovered clinically and biochemically for more than three years; ten had been in a similar condition for less than three years. Together these form a group of 37 per cent of the whole. The disease of six patients is still in its first phase of activity. Four patients were thought to be well until stool analyses showed steatorrhea. These patients are in a quiescent phase of the disease, which, if in adult life it becomes reactivated, is usually diagnosed as idiopathic steatorrhea. To such the name latent celiac disease should be given. Patients who have had celiac disease tend to remain dwarfed, but their intellect is not affected.

Sugar Content of Cerebrospinal Fluid in Meningitis.—Reduction in the dextrose content of the cerebrospinal fluid is a familiar observation in all forms of meningitis, but the cause of this has not yet been definitely determined. Hendry reviews the literature, from which it seems unlikely that lessened permeability of the choroid plexus to the passage of sugar into the cerebrospinal fluid is the cause for the reduction. The evidence points to the reduction being due to the action either of bacteria or of leukocytes. The author devised tests to determine if there is an alteration in the permeability of the blood brain barrier to dextrose, if the action of bacteria is the cause of the reduction or if the presence of leukocytes is responsible for the reduction. He observed that in the early stages of cerebrospinal fever a greatly increased cell count and a positive bacterial culture are almost invariably encountered. At this time the sugar content is extremely low. The patients were treated with sulfanilamide, and a sterile cerebrospinal fluid was found on the second or at the latest on the third occasion on which lumbar puncture was performed. As at this stage of the illness the cell count is still high and the sugar content, though rising, well below normal limits, these observations would suggest that meningococci are not responsible for the breakdown of dextrose. In cases of meningococcal meningitis the cell picture of the fluid changes from being almost entirely polymorphonuclear to one composed largely of lymphocytes. In the early stages there is great reduction in the cerebrospinal fluid sugar content, while in the later stages when the exudate is largely composed of lymphocytes the sugar content approaches the normal level. In conditions such as benign lymphocytic meningitis, in which there is a purely lymphocytic exudate, there is no sugar reduction in the spinal fluid. Two cases of meningitis due to *Bacillus coli* showed complete absence of cerebrospinal fluid sugar, an occurrence which might be expected as two factors are operative: a strongly glycolytic organism in addition to a large polymorphic cellular exudate. In tuberculous meningitis conclusions are not so easily drawn but it is suggested that, as the tubercle bacillus has practically no power to break down sugar and as it is present in the cerebrospinal fluid only in small numbers, the part that it

plays in reducing cerebrospinal fluid sugar need not be considered. In the early stages of the disease the cellular exudate in the spinal fluid is largely lymphocytic and at this time the sugar content of the fluid is not greatly below normal. As the disease progresses to its fatal issue there is an increase in the number of polymorphonuclear cells and a simultaneous decrease in the sugar content. It is concluded that polymorphonuclear leukocytes possess powers of glycolysis and their presence is the reason for reduced cerebrospinal fluid sugar in purulent meningitis and for the progressive decrease in its sugar content in tuberculous meningitis.

Distribution and Character of Lesions of Poliomyelitis.—From a microscopic examination of the central nervous system in eight cases of poliomyelitis Swan makes the following remarks: The distribution of the meningeal infiltration is modified by the flow of the cerebrospinal fluid. Necrosis of nerve cells in the cerebral cortex is confined to the area gigantopyramidalis, and almost entirely to the Betz cells of that area. The rhinencephalon (including the olfactory bulbs) was surprisingly but slightly involved. Lesions were found only in the anterior perforated substance and in one instance in the cornu ammonis. Evidence for the process of neuronophagocytosis was seen in the pigmented cells of the locus caeruleus. Selective affinity of the virus for cells of the motor type is not absolute except perhaps in the cerebral cortex and the cerebellum. However, motor cells are more often and more severely involved than sensory cells. The medial longitudinal bundle seems an important path for the spread of the pathologic process. Infection by the virus of poliomyelitis by the olfactory route is either less common than was formerly thought or is not commonly fatal; i. e., the virus is localized in the olfactory bulbs and immunization takes place. Cases with initial bulbar palsy probably result from infection by the tonsillopharyngeal route. There is no fully conclusive evidence for infection by the gastrointestinal route in man.

Electric Convulsion Therapy in Schizophrenia.

Fleming and his associates point out that Cerletti and Bini reported in 1938 that the passage of a strong alternating current through the head usually resulted in immediate unconsciousness followed by a prolonged fit. They worked out a technic whereby this phenomenon could be used to replace the injection of convulsant drugs in the treatment of schizophrenia and administered shocks to several hundred patients. Fleming and his associates tested this method of electrical convulsion therapy on five schizophrenic patients. They administered seventy-five shocks, as a result of which there have been fifty major convulsions and twenty-five minor seizures. The major convulsions are similar to spontaneous ones and are followed by complete amnesia for the shock. No untoward results have been observed. The claims of Cerletti and Bini are confirmed; the method is technically effective, simple and safe and arouses no fear or hostility in the patients. No attempt is made to assess the therapeutic value of the method, which Cerletti and Bini state is the same as that of metrazol.

Dark Adaptation as Test of Vitamin A Deficiency.

Harris and Abassy discuss experiments carried out to reinvestigate the reliability of dark adaptation tests for detecting deficiency of vitamin A. The Birch-Hirschfeld photometer was used, with several improvements in technic: a large screen was used for the "bleaching," and during the test the subject's attention was kept directed to the position of the quincunx. Two precautions were taken: 1. Each subject was reexamined repeatedly and the initial value not accepted until it had been found to remain relatively constant on successive occasions. 2. To check the specificity of the result, subjects found to be subnormal were divided into two groups, half being treated with the vitamin and the other half kept as controls. The criterion accepted for subnormal dark adaptation was a diaphragm reading of 6 or over (with wedge set at 5) after ten minutes in the dark; the reading immediately after the "bleaching" was considered of less value, mainly because of its rapid rate of change. Control tests indicate that, under the ordinary working conditions, previous exposure to light had no important influence on the results. Among middle-class adults cases of lowered dark adaptation seemed relatively rare and readings were not improved beyond the usual normal by treatment with vitamin A. The following evidence is offered that the method of the dark adaptation test is sound in principle: 1. Children found subnormal returned slowly to normal after treatment with large

amounts of vitamin A, whereas an equal number of controls left untreated remained subnormal. 2. Scrutiny of earlier results on children attending elementary schools revealed a heretofore unsuspected correlation with their individual dietary histories—among children having two thirds of a pint of milk at school 67 per cent were normal on test, whereas of those having one half pint or less only 37 per cent were normal. 3. The incidence of lowered dark adaptation among the various social classes examined has borne a relation to their dietary intake. 4. Attention is drawn to the work of other investigators proving a correlation between deficient intake of vitamin A and lowered dark adaptation. It is concluded that the theoretical basis of the test is reliable, although the apparatus and technic can be further improved. The dark adaptation test is capable only of detecting deficiency and not of assessing different levels of normality. Since the test is relatively intricate it is not suitable for rapid routine use by school medical officers. It can have its application in surveys on small selected samples of the population to confirm the supposition of deficient dietary intakes or for diagnosis in the clinic. Deficiency seems less common among adults than in children.

Clinical Use of Triphenylchloroethylene.—Macpherson and Robertson used triphenylchloroethylene in this investigation because its action is greater and more prolonged than that of triphenylethylene. The forty-one cases treated included amenorrhea, menopausal symptoms, atrophic vulvitis or some similar condition, atrophic rhinitis and cases in which it was desirable to inhibit lactation. Triphenylchloroethylene was prepared for oral use in tablet form, each tablet containing 200 mg.; in ampules containing 250 mg. dissolved in 5 cc. of sesame oil, suitable for injection, and in cocoa butter made up in the form of vaginal suppositories, each containing 100 mg. Tablets are given after meals, and as many as nine a day may be given without any fear of producing toxic effects. Two injections are given a week apart to begin with, followed by a third injection three weeks after the second. Subsequent injections may be given at intervals of three or four weeks according to the response produced. Vaginal suppositories are used nightly for the first fourteen days of treatment and then on alternate nights or every third night, as determined by the progress made. In each of the four cases of amenorrhea treated there have been periods of withdrawal bleeding between the courses of treatment. The total dosage that has produced this result has been from 12,000 to 16,000 mg. Of the patients with vulvitis and vaginitis, seven had atrophic rather than primarily infective vulvitis and vaginitis. The eighth patient in this group complained of intense itching of the vulva. The drug was given orally in four cases and by injection in four. The amounts used in each course of treatment were not constant throughout this group, but the variations were not wide. The result of the treatment in almost every case was complete relief from symptoms and in seven of eight cases the local condition was obviously improved. The patients with menopausal symptoms all received the drug in tablet form, from 200 to 1,800 mg. (from one to nine tablets) being taken daily for, in some cases, several successive courses of from four to five weeks. The effect of the drug was noticed within two days of the start of treatment, and after the average course, which lasted from three to four weeks, the action of the drug was maintained for another two weeks before any recurrence of symptoms was noticed. Triphenylchloroethylene was given to twelve patients to inhibit or stop milk secretion, six by mouth and six by injection. In those treated by mouth the total dosage has been about 4,000 mg. given over a period of five or six days. Where treatment was begun shortly after delivery, the breasts remained soft and painless in four of six cases. Of the other two patients, one experienced discomfort on the third day and the other secreted a considerable quantity of colostrum for three days but no milk. Of two patients, treated by injection on the first day of the puerperium, the breasts showed no engorgement and remained painless. Where lactation was already established, treatment by tablets or by injection of from 250 to 300 mg. led to cessation of milk secretion after from three to five days, and in no case was there any recurrence. Triphenylchloroethylene has no definite toxic effects and can be administered in large doses or over a long period. The duration of action by mouth closely approximates that of stilbestrol. By injection, however, the duration is singularly prolonged; after

500 mg., by the technic described, effective action persists for from six to nine weeks. By this method, therefore, a very small dosage is sufficient to maintain a continuous high level of estrogen activity.

Congenital Neurosyphilis.—Borrie and McGeorge recently encountered two juvenile cases of congenital syphilis of the nervous system, one of the parenchymatous and the other of the interstitial type. The boy, aged 15 years, presented a typical instance of dementia paralytica, while his half-sister, 4 years, died from meningovascular syphilis. These children were the offspring of the same mother. There were no other children in the family.

Tellurite Test for Diphtheria.—Murray compared the results of the tellurite test for diphtheria with the bacteriologic results of an unselected consecutive series of pharyngeal exudates. Owing to the long distances separating many practitioners from laboratories in South Africa and the consequent delay in receiving laboratory confirmation of a diagnosis of diphtheria, the author felt that the test if its reliability was confirmed would be especially valuable under the conditions existing in South Africa. The results of the test in a series of sixty-two cases show thirty-eight positive direct tellurite tests, but eleven (28.9 per cent) of these were neither bacteriologically nor clinically acceptable as cases of diphtheria. In twenty-four cases giving a negative tellurite test, five (20.8 per cent) were definite cases of diphtheria. Putting the results in another way, 84.3 per cent of the diphtheria cases gave positive results, but on the other hand 36.6 per cent of nondiphtheritic cases also gave positive results. These results correspond closely to those obtained by Tombleson and Campbell, by Cooper and his associates and by Tynan (1939). With such a high percentage of error in each direction it seems unlikely that the test is of any practical value. Reliance for the diagnosis of diphtheria in this area at least must continue to be placed on the clinical and bacteriologic observations. The varying reports made on results of the test in different series since Manzullo's publication would appear to bear out the percentage error. In Johannesburg at least it has failed to provide any reliable assistance in the more speedy diagnosis of diphtheria.

Behavior of Basophilic Erythrocytes in Surgical Diseases.—According to Kamioka the basophilic erythrocytes, that is, polychromatophilia and basophilic stippling, have been regarded by some as a degenerative process of the erythrocytes, by others as a sign of regeneration. Basophilic stippling was observed first chiefly during lead poisoning but later also

in anemias and in various renal disorders. The author decided to investigate their occurrence during surgical disorders, particularly those of the kidney. He made investigations on forty healthy persons and on 204 surgical patients. Among the latter group there were thirty with acute pyogenic infection, fifty with tumors, mostly cancers, twenty-one with extrarenal surgical tuberculosis, sixty-seven with renal tuberculosis and twelve with other surgical diseases of the kidneys. In the healthy persons the average number of basophilic erythrocytes was 159. In the acute pyogenic infections the basophilic erythrocytes were considerably increased, the average number being 432. In the mild and localized pyogenic infections the increase was mild, but in the cases of sepsis, particularly those in which the erythrocyte count and the hemoglobin value were reduced, the increase in basophilic erythrocytes was great. The increase was especially noticeable after surgical removal of the focus and evacuation of the pus. In sepsis which had a lethal outcome there was no increase in the basophilic erythrocytes. In the patients with cancer the basophilic erythrocytes were slightly increased, but the increase became greater following the radical removal of the cancer. In extrarenal surgical tuberculosis (chiefly tuberculosis of the lymph nodes, bones and joints) the increase in basophilic erythrocytes was moderate. In the patients who had undergone nephrectomy for renal tuberculosis the author observed that the increase in basophilic erythrocytes was the more noticeable the less advanced was the destruction of the renal parenchyma. In the nontuberculous surgical diseases of the kidney the basophilic erythrocytes showed a more or less pronounced increase even in the absence of anemia and renal insufficiency. The author reaches the conclusion that the increase in the basophilic erythrocytes must be regarded as a regenerative process of the erythrocytes.

*Ulcers of Second Portion of Duodenum. J. Demirleau.—p. 856.

Ulcers of Second Portion of Duodenum.—Brulé and his associates report a case of ulcer of the second portion of the duodenum in which gastro-enterostomy was successfully performed. A man aged 29 had severe attacks of pain for five years that appeared but once each year, lasted about twenty days and were eased by vomiting. The last onset was attended by hematemesis that made blood transfusion necessary. Roentgenograms revealed a deep cavity at the interior edge of the upper part of the second portion of the duodenum. Two thirds of the way above this cavity the second portion was found narrowed with an irregular marginal configuration, contrasting with the dilatation noticeable in the lower part of the second and in the third portion. Duodenal ulcers of the second portion are usually found between the upper bend and the ampulla of Vater. They are terebrant, affect the pancreas and are accompanied with serious manifestations of periduodenitis and pancreatitis. They often appear as huge tumoral masses with hyperemia of tissues and pronounced vascularization. The authors stress the importance of a differential x-ray diagnosis directed to duodenal diverticula, to the dilatation of the ampulla of Vater, especially when it attains significant dimensions, and to certain bulbar ulcers, since in consequence of inflammatory reactions or adhesions the shape and contour of the bulb may be completely modified. Complications in duodenal ulcers of the second portion may be due to stenosis of the bile duct and duodenum, to pancreatitis and to perforation. Hemorrhages are frequent. The choice between medication and surgical intervention is determined by the consideration of the frequency of hemorrhages and the presence of a considerable inflammation in the area about the ulcer. The surgical operation of choice depends on the presence or absence of the tumoral mass, its site, its size and the extent of vascularization. In the present case the presence of a crater across the anterior wall large enough to allow a finger to pass through and the considerable degree of vascularization rendered excision impossible and made gastro-enterostomy the surgical method of choice.

Ulcers of Second Portion of Duodenum.—Demirleau reports four cases of duodenal ulcers in which, on clinical and radioscopic examinations, gastrectomy with exclusion was performed. The age of the patients ranged between 28 and 56 years. In all patients gastric or epigastric pains had made their first appearance in early infancy (second or third year). In all four cases large ulcers were discovered in the second portion of the duodenum, three times with implications of pancreatitis. In one case a stenosis was found below the upper bend, large enough to prevent passage of a finger. In another case the base of the ulcer was situated 2 cm. above the ampulla of Vater and the ulcer had eaten its way into the bile duct causing an opening of more than 1 cm. All cases had fatal endings, three from complications (pneumonia, peritonitis, pleurisy), the fourth from an involvement of surgical complications. Four necroscopic views with reduced replicas are shown.

Adrenal Reactivation by Enervation of Sinus Caroticus.—Léger reports two cases of adrenal insufficiency. A woman aged 52, who had attacks of feebleness and the pigmentation characteristic for adrenal insufficiency, did not show noticeable improvement from treatment with adrenal cortex extract. Enervation of the sinus caroticus was made on the right side. The emaciated patient tolerated the operation well. Four months later the facial pigmentation had greatly diminished but in other parts of the body the pigmentation was still largely unchanged. The patient had gained 15 Kg., the arterial tension had increased and the asthenia had completely disappeared. A man aged 40, who had pulmonary tuberculosis and later developed the symptoms of Addison's disease, namely pigmentation, asthenia, digestive disturbances and low arterial tension, experienced only a slight amelioration of short duration from adrenal cortex extract, so enervation of the sinus caroticus, was performed on the right side. The patient's appetite increased, and vomiting and constipation subsided. The arterial tension did not change much and the pigmentation persisted, although the patient declared that it showed a tendency to diminish. The author reviews the literature on the enervation of the sinus caroticus in Addison's disease. He concludes that the results justify further trials of this method.

Late Accidents After Use of Oil Suspensions of Gold Salts.—Rossel reproduces a roentgenogram which shows small, well circumscribed spots of great density on both sides of the pelvis, at the level of the iliac crest. These spots were explained when the patient recalled that two years before she had received intramuscular injections of an oil suspension of calcium aurothioglycolate. The injections had been made into the gluteal region and the patient had received no other injections into this region; it cannot be doubted that the small spots correspond to the oil droplets of gold salts. What makes the case especially noteworthy is the long persistence of the oil depots—two years—and the local tolerance. The oil suspension of calcium aurothioglycolate seemed to be encysted like grains of granulated metal. The author thinks that this case is probably far from being unique and that it might explain why complications seem much less frequent with oil suspensions than with aqueous solutions of gold salts. In numerous cases this is probably due to the total or almost total absence of absorption in the case of the

oil suspensions. This in turn raises the question of the therapeutic efficacy. The author concludes that the problematic advantages of the oil suspensions of gold salts do not counterbalance the grave dangers which may appear even long after the treatment.

Endogenic Origin of Carbon Monoxide in Blood.—Loeper and Gilbrin investigated the carbon monoxide content in various types of anemia. In a case of hemogenic anemia and in four cases of cancerous anemia the value was increased. It was increased also in several cases of polyglobulism in respiratory disturbances, in alcoholic cirrhosis, in a case of acute polyarthritis, in cases of epilepsy, in a case in which suicide had been attempted by means of barbitol, and in cases of diabetes and oxalemia. However, the authors emphasize that the carbon monoxide content of the blood is increased in only some of the cases. Because of the absence of exogenic causes, the authors believe that the increased carbon monoxide content results from disturbances in the tissue metabolism. Carbon monoxide is a product of the incomplete combustion of substances rich in carbon. The fact that an increased carbon monoxide content of the blood is encountered in subjects with pulmonary or circulatory disorders confirms this hypothesis. The substances which more than others can give rise to carbon monoxide are the glucides. After reviewing experimental studies on this problem, the authors say that they are in accord with the theory which ascribes the excess of carbon monoxide to a disturbance in the metabolism of the glucides. The frequency of an excessive carbon monoxide content in the blood of patients with diabetes supports this hypothesis.

Insulin in Tabetic Crises.—Binswanger reports observations on a patient with severe tabetic crises, in whom only fever therapy was effective. However, the effects of the fever therapy were of short duration. Insulin shock therapy was resorted to and following this the tabetic crises subsided for a time. When the pains recurred it was decided to try to counteract the crises by a "weakened" administration of insulin. It was found to be sufficient for the hypoglycemia to produce a slight somnolence and profuse sweating. The insulin should be extended over a period of from two to three weeks and should be begun when the tabetic pains have been absent for several days, for attacks of lancinating pains, persisting for several days, apparently cannot be broken off by insulin therapy. The insulin treatment improves the general condition and puts the patient into a euphoric mood. If insulin should prove effective in other cases of tabes with lancinating pains, it would be a distinct advancement in the treatment of painful tabetic crises.

Staphylococic Toxoid in Treatment of Staphylococic Infections. P. Ritossa and G. Polistina.—p. 1362.

Toxoid in Staphylococic Infection.—Ritossa and Polistina resorted to staphylococic toxoid in seventy-six cases of cutaneous and surgical staphylococic infections (furuncles, abscesses, infected sores, infected wounds and osteomyelitis) or staphylococic septicemia. The authors used toxoid with an antigenic value which corresponded to 16 staphylococci.

for each cubic centimeter of the preparation. The presence or absence of allergy was ascertained by subcutaneous injection of 0.1 cc. of staphylococcic toxoid. In the absence of allergy the treatment consisted of five subcutaneous injections at intervals of five days in increasing doses of 0.5, 1, 1.5 and 2 cc. of toxoid up to a total dose of 5 cc. for the entire treatment. In rare cases the treatment was repeated. It was administered alone or in association with surgical operation, according to indications. The treatment was well tolerated. It rapidly controls local and general staphylococcic infections. In surgical infections it rapidly accelerates the processes of suppuration, detersion and healing of infected tissues or bone, after the operation. Septicemia is rapidly controlled. The author advises the treatment in the various forms of cutaneous and surgical staphylococcic infections and in general staphylococcic septicemia.

Inversion of Uterus Post Partum. L. A. Balasquide and W. R. Gelpi.—p. 3.

*Acute Mesenteric Lymphadenitis. J. Noya Benitez.—p. 8.

Acute Mesenteric Lymphadenitis.—Noya Benitez observed nine children ranging in age from 5 to 12 years who were suffering from acute mesenteric lymphadenitis. The patients reported an attack of cold and cough for a few days preceding the onset of acute abdominal pain which developed in association with nausea, vomiting, fever and tenderness and muscular resistance at the right lower quadrant. They had a history of similar recurrent and subacute attacks in the past. Leukocytosis existed in all cases. Appendectomy was performed during the first twelve hours after the patients entered the hospital. Acute appendicitis coexisted with acute mesenteric lymphadenitis in three of the cases. In all cases appendectomy caused the symptoms of acute mesenteric lymphadenitis to subside and controlled the attacks, and the results appear to be permanent. The author found it difficult to differentiate between acute appendicitis and acute mesenteric lymphadenitis. The two conditions frequently coexist. The attacks of acute mesenteric lymphadenitis are controlled by appendectomy. He concludes that immediate appendectomy is the proper treatment of acute mesenteric lymphadenitis, whether or not the disease coexists with acute appendicitis.

Disturbances in Bone Growth Following Renal Changes.—Werner describes observations on a child, aged 1 year, who had a severe renal disorder presenting the aspects of chronic pyuria. The child was under observation for about a year, during which time disturbances in growth and osseous changes developed. The clinical aspects seemed to place the disorder in the group of renal rickets (Parsons' type III). Necropsy revealed a severe chronic nephritis, hyperplasia of the parathyroids and, in the bones, osteitis fibrosa generalisata (Recklinghausen). The author raises the question whether some cases of renal rickets actually are true rickets or whether a disease entity exists that develops from the metabolic disturbance, which in turn is caused by the impaired renal function and by way of the hyperplasia of the parathyroids and which becomes manifest either in the form of rachitis-like growth disturbances in the bones or in the form of osteitis fibrosa generalisata. He suggests that cases of rickets which prove resistant to vitamins might perhaps find their explanation in this manner. The metabolic disorder or the parathyroid hyperplasia would not necessarily have to be of nephrogenic origin.

Localization of Foreign Bodies by Double X-Ray Exposure.

Shiga says that foreign bodies of hard substances deep within the body can be localized exactly by his method of simultaneous double x-ray exposure. The theoretical foundation of this method is almost like that of the shifting methods of exposure devised by other investigators; however, the author adds a further theoretical development and geometrical explanations. The error of experimental observation totals 0.95 per cent and amounts to only 1 or 2 mm. of the true length of the object. This method of double exposure by means of parallel x-ray tubes can be used not only for the localization of foreign bodies but also in the diagnosis of digestive, urogenital and orthopedic disorders. Furthermore, it can be used for industrial purposes, such as for the inspection of cast-metal work.

Vertebral Column and Eunuchoidism.—Lindgren reviews two cases of eunuchoidism, one concerning a woman, the other one a man. In the woman a roentgenogram of the tubular bones made at the age of 32 had revealed several open epiphyses, but at the necropsy ten years later they were found closed. In the male patient earlier roentgenograms were not available. In the woman the author gave his attention chiefly to the vertebral column. He observed among other changes irregular ossification of the epiphysal plates; that is, conditions indicative of inhibited development of the vertebral bodies. He thinks that this inhibition is probably the result of gonadal hypofunction. However, he does not think that the inhibited ossification produced a noticeable increase in the size of the vertebrae. In eunuchoidism the extended growth of the long tubular bones, as the result of the persistence of the epiphyses, contrasts with that of the vertebral column and this explains the typical eunuchoid proportions of the body. This accords with Schmorl's opinion, according to which the epiphysal plates of the vertebrae cannot be compared with the epiphyses in the long bones and do not play a part in the longitudinal growth of the vertebral bodies. In the reported case it is noteworthy that the vertebral column still exhibited signs of continuous growth at a time at which growth in the long bones was already completed. The author concludes that in eunuchoidism, probably as a result of gonadal insufficiency, the growth of the long tubular bones progresses unchecked. The epiphysal plates of the vertebrae, although they do not have the same functional significance as have the epiphyses of the long bones, apparently are likewise subject to incretory regulation, for in the reported case the gonadal hypofunction resulted in an inhibition of their ossification. The author recommends studies on the epiphysal plates of the vertebrae in other endocrine disorders.

Advanced and Full Term Extra-Uterine Pregnancies.

Pütz reports three cases of extra-uterine pregnancy that exemplify the diagnostic difficulties encountered in ectopic gestation. He stresses the need of observing features suggestive of extra-uterine pregnancy. Among these are poor physical condition, an intact portio at the end of pregnancy, exceptionally vigorous fetal movements that cause no pain, pain during the second half of pregnancy (not always present), Cullen's sign, and the distinct palpability of fetal parts under the abdominal wall. He thinks that extra-uterine pregnancies are due for the most part to inflammatory conditions in the oviducts or pelvic organs of maturer women who either have borne no children or have undergone periods of sterility after previous parity.

*Observations on So-Called Lactation Neuritis. M. Glees.—p. 615.

Pathogenesis of Myopia.—Lindner cites evidence which suggests that only that type of close work promotes myopia which involves an intense metabolism of the retina. Reading, with its continuous change of pictures, results in much greater metabolism than does looking at the same picture. The greater exertion of the visual organ is accompanied by a greater serous perfusion of the choroid. Watchmakers are almost never myopic; the pictures which they observe remain constant and the metabolism of the retina is consequently less intense than is the case in reading. Sewing likewise calls for less exertion of the retina than does reading and this explains the low percentage of myopia among seamstresses. To prevent myopia or arrest its progress, the work of the retina must be made as easy as possible. Even slight astigmatic defects should be carefully corrected; the best possible illumination should be provided; prolonged close work should be interrupted by frequent recesses, and venous stasis in the region of the head, such as is brought on by a bent-over posture, should be avoided.

So-Called Lactation Neuritis.—Glees reviews the symptomatology. He says that during the puerperium or shortly thereafter there may develop, accompanied by headaches, an impairment of the visual acuity of one or both eyes. Examination discloses optic neuritis, peripheral contractions of the visual field and central scotomas. Occasionally the bulbi are sensitive to pressure and the movements of the eyes may be painful. The disorder subsides in the course of weeks or months and the visual acuity is largely restored. Thus the prognosis is relatively favorable. The etiology is unknown. He reports three cases of lactation neuritis observed at his clinic during 1938. In the first case the disorder developed eleven weeks after delivery and five weeks after the child had been weaned. In the second case it appeared four weeks and in the third case six weeks after delivery; both of the women were still nursing their infants when the eye disorder developed. All cases were characterized by severe changes in the papilla and in two cases there existed vascular changes and retinal edema in the surroundings of the papilla and along the large vessels. In view of the fact that vascular changes, particularly contraction of the arteries, have been observed also by others who have studied lactation neuritis, the author concludes that vascular changes play a part in the pathogenesis of this optic neuritis. To be sure, this does not explain why they appear during the period of lactation. None of the hypotheses give a satisfactory explanation and the author regards a direct connection between the disease of the optic nerve and the lactation as doubtful. He accepts as most plausible that weakening of the organism by gestation, delivery and puerperium provide the basis for some infectious impairment of the optic nerve.

Roentgenologically Visible Calcifications of Cardiac Valves.—Hoffmann says that there are few records of roentgenologically visible cardiac calcifications. He describes his own observations in two cases. In the first, roentgenoscopy disclosed nothing abnormal on the lungs or the diaphragm. However, a dense shadow the size of an almond was observed

in the left half near the center of the heart. This shadow moved up and down and when the patient was turned the shadow could neither be separated from the heart nor even transferred into its periphery. Furthermore, inspiration did not change the position of the shadow. The regularly pulsating movement of the calcium shadow was considerably more extensive than that of the cardiac outline. During lateral exposure the shadow made an almost vertical elliptic rotation. The roentgenogram indicated that the shadow represents a calcification of the mitral valve. The roentgenologic diagnosis of calcification of the mitral valve was supported by the clinical examination, which indicated a mitral stenosis and insufficiency. An endocarditis during childhood is regarded by the author as the cause of the mitral calcification. In the second case a dancing calcium shadow the size of a bean led to a more thorough examination. In view of the position of the shadow and of its dancing movements, the author assumes a calcification of the aortic valve. He thinks that a calcification of the coronary arteries can be ruled out because the movement of the shadow was more extensive than that of the edge of the heart.

General Irradiation in Cutaneous Tuberculosis.—Küllmer and his associates state that, at the Giessen sanatorium for patients with lupus, observations extending over twenty-five years have demonstrated that systematic and correctly apportioned heliotherapy is the most important factor in the successful treatment of cutaneous tuberculosis. Attempts were made to provide the lupus patients during the sunless periods with a substitute for sunlight. The authors describe the various types of therapeutic lamps that were used. It was their aim to determine what type of radiation was necessary to produce a certain biologic effect. They describe the method used for general irradiations of 150 patients during the winter 1938-1939. The long ultraviolet waves were of great value in the treatment of patients in whom the cutaneous tuberculosis is complicated by pulmonary lesions. They dispensed with the strong irritative action which the short ultraviolet rays exert on the skin. Their observations correspond with the fact that sun baths during the morning hours are better for patients with cutaneous tuberculosis than are sun baths when the sun stands highest, that is, when the wavelengths are shorter; furthermore, the favorable therapeutic results obtained during spring in the high mountains tend to add further proof. They are convinced that in cases of cutaneous tuberculosis the weakening of the short ultraviolet waves is advantageous. They hope that a type of radiation may be found that can be used in cases of active pulmonary processes.

Metrazol Therapy in Narcotic Poisoning.—According to Kutschera-Aichberger, victims of barbituric acid poisoning may die because the dosage of the drugs usually administered is insufficient to rouse them from their coma and thus allows post-narcotic pneumonia to develop. He was successful in forcing

comatose persons into consciousness by persistent administration of unusually high doses of from 5 to 10 cc. of metrazol at hourly intervals without inducing convulsions, though the total dosage was as high as 110 cc. within ten hours. In two cases reported from a larger number, the author was able to restore to consciousness and life two women, aged 37 and 31, who had attempted suicide by means of barbitol and illuminating gas, by injections of 10 cc. of metrazol given intravenously every hour. In the one case supplementary measures consisted of intramuscular injections of 10 cc. of metrazol, carbon dioxide inhalations (seven an hour) and a subcutaneous injection of physiologic solution of sodium chloride (2 liters). Nourishment was supplied by a nasal instillator in the form of sugar solution and black coffee. The author stresses the necessity of large doses of metrazol in intoxication from barbituric acid derivatives, the therapeutic value of carbon dioxide inhalation and the need of nourishing comatose patients who cannot be roused on the first day. He cautions against the use of high doses in cases of self poisoning by other means. Barbituric acid and its derivatives, he found, showed a tolerance of metrazol far exceeding the usual tolerance limit, without provoking spasms.

Physiologic Observations on Caisson Workers.—Marquort and Rietz observed caisson workers exposed to pressures of 3.75 atmospheres. They found that such pressures do not cause an increase in the basal metabolism during the time the worker is in the caisson or as the result of the daily work under such high atmospheric pressures. Observations on the pulmonary ventilation revealed a greatly increased respiratory volume with a simultaneous decrease in frequency and thereby corroborated the assumption of a deepened respiration during the time the worker is in the caisson. However, there was no increase in the vital capacity during the stay in the caisson or as the result of several months' work in it. Studies on the circulation during the stay under excess pressure revealed a decrease in the frequency of the pulsation in spite of hard physical labor. Simultaneously there existed a tendency toward decrease in blood pressure. Electrocardiographic records made while the workers were under excess pressure revealed a positional change of the heart in the form of a turn of the sagittal axis, a change that is indicative of a lowering of the diaphragm. There were no changes in the condition of the stimulus or in the contraction. Furthermore, caisson workers, even those who had done this type of work for years, were free from electrocardiographic changes. The red blood pictures of caisson workers revealed a tendency to a decrease in erythrocytic values during the stay in the caisson, but there were individual differences in the severity. Following a return to ordinary atmospheric pressure, normal erythrocytic values were found and there were no signs that anemia developed after daily work in the caisson. The refractometric blood protein values, which were determined in order to clarify the concentration of the blood, were increased under excess atmospheric pressure in the majority of cases. Thus there is no foundation for the assumption of a hydremia. The observed increases in the protein values were the result of the muscular exertion. The blood sedimentations show a normal course. The fluctuations in the sodium chloride and the bilirubin values likewise are within the limits of the physiologic norm during stay in the caisson.

*Combined (Simultaneous) Immunization Against Tetanus. L. Otten and I. P. Hennemann.—p. 391.

Immunization Against Tetanus.—Otten and Hennemann cite investigations which show that the development of active immunity against tetanus is interfered with by a single as well as by a repeated serum injection and that immunity is not always detectable as late as from thirty-one to forty-one days after the first injection of formaldehyde toxoid. They decided to solve this problem experimentally by determining the antitoxic values during the first six weeks after the commencement of immunization. They tried eight different methods. They stress the following points: 1. As in immunization against diphtheria, the development of active immunity against tetanus by formaldehyde toxoid appears to be inhibited by the presence of a passive immunity. 2. Experimental research in guinea pigs proves that the third to the sixth week constitutes the critical period, the passive immunity becoming exhausted while active immunity has still not reached the required level. 3. With three injections of formaldehyde toxoid at ten day intervals, the first two followed by injection of serum after twenty-four hours, this gap can be bridged, the passive immunity passing into the active without interruption. 4. The inhibitory action of the passive immunity has to be attributed to the antitoxin itself, whether of heterologous or of homologous origin. 5. Apart from this specific factor, heterologous serum, by its foreign protein content, provides a nonspecific factor, either inhibiting directly or, on repeated administration, indirectly by interference of a protein antiprotein reaction. 6. As the course of the response to combined immunization in man has not been studied with sufficient accuracy up to now, this method should not be applied universally until a systematic research, pursued over the whole critical period of the third to the sixth week, has proved that the antitoxin can indeed be maintained continuously at a satisfactory level. 7. Even if this should appear practicable, systematic active immunization deserves recommendation for all occupations particularly exposed to the risks of tetanus infection and above all for military forces.

Renal Rickets. T. Gordh.—p. 376.

Atrophic Arthritis Secondary to Congenital Subluxation of Hip.—Wiberg explores roentgenologically the relation of congenital subluxation of the hip to the evolution of atrophic arthritis in eighteen cases in which x-ray examinations could be repeated in the course of from fifteen to thirty years. The successive film evidence for three of the cases is presented. According to the author, sclerosis in the roof of the socket seems to be the first sign of arthritis and appears before there are any demonstrable changes in the head, but after these have occurred subsequent changes are more rapid in this region. Destruction of the cartilage need not precede sclerosis. However, the author has observed no case in which there was pronounced cartilage destruction in the absence of sclerosis. The presence of a double floor in the socket cannot be established in all cases of subluxation. After the process of arthritis has set in, beak-formed osteophytes occasionally develop on the lateral margin of the roof but fail to offer structural support. Capital deposits seen in the film were always situated in the lower part of the head and appear in the film as parrot beaks. The resultant form of the head depends to the highest degree on its initial form.
